Outline

## Notes

Week 11: Eigenvalues and eigenvectors:
complex numbers and random walks

Course Notes: 6.2

Goals: More practice finding eigenvalues and eigenvectors; expanding these to the complex numbers; using them in the context of random walks.

Note: because these computations get pretty long, we will skip many of the repetitive parts in lecture. We'll focus on newer material, and leave it to you to review older content

## Course Notes 6.2: Eigenananyssis Simplifies Matrix Powers

Random Walks - Review

- $\mathbf{x}_{n}=\left[\begin{array}{c}p_{1} \\ p_{2} \\ \vdots \\ p_{k}\end{array}\right]$ and $p_{1}+p_{2}+\cdots+p_{k}=1$

Probability vector, at time $n$

- $\mathbf{x}_{n}=P \mathbf{x}_{n-1}$
- $\mathbf{x}_{n}=P^{n} \mathbf{x}_{0}$

## Course Notes 6.2: Eigenanalysis Simplifies Matrix Powers

Random Walks and Eigenvalues

What if $\mathbf{x}_{0}$ were different?

|  | from | pass fail |
| :---: | :---: | :---: |
|  | to | $\frac{1}{2}$ |
| pass | $\frac{1}{3}$ |  |
| fail | $\frac{1}{2}$ | $\frac{2}{3}$ |
| $\lambda_{1}=\frac{1}{6}, \mathbf{k}_{1}=\left[\begin{array}{c}1 \\ -1\end{array}\right] ;$ | $\lambda_{2}=1, \mathbf{k}_{2}=\left[\begin{array}{l}2 \\ 3\end{array}\right]$ |  |

$\lambda_{1}=\frac{1}{6}, \mathbf{k}_{1}=\left[\begin{array}{c}1 \\ -1\end{array}\right] ; \quad \lambda_{2}=1, \mathbf{k}_{2}=\left[\begin{array}{l}2 \\ 3\end{array}\right]$

Your initial state is $\mathbf{x}_{0}=\left[\begin{array}{l}1 \\ 0\end{array}\right]$. What happens after many tests?

Eigenvalues of Probability Transition Matrices

Theorem
If $P$ is a transition matrix (non-negative entries with all columns summing to one) that in addition has all positive entries then $P$ has an eigenvalue 1 with a single eigenvector $k_{1}$ that can be chosen to be a probability vector. All other eigenvalues satisfy $|\lambda|<1$ with eigenvectors with components that sum to zero. Thus,

$$
\lim _{n \rightarrow \infty} x_{n}=k_{1}
$$

for any $x_{0}$. That is, $k_{1}$ is an equilibrium probability.
[Proof, of sorts]
In short: that last example was typical. As long as a probability matrix has no zeroes:

- Probability matrices have 1 as an eigenvalue
- There will be some equilibrium that the system will reach in the long run, regardless of initial state, corresponding to an eigenvector of 1 .

## Course Notes 6.2: Eigenanalysis Simplifies Matrix Powers

Equilibrium Probability

Which of these random walk models seems likely to have
an equilibrium probability? Is it clear what would it be?
In any given day, your odds of dying are 1 in 1,000.

Equilibrium Probability

Find the equilibrium probability of the system

In a relationship or not, by year. |  | single | single | partnered |
| :---: | :---: | :---: | :---: |
|  | partnered | .4 | .25 |
|  |  | .75 |  |

Theorem
If $P$ is a transition matrix that in addition has all positive entries then $P$ has an eigenvalue 1 with a single eigenvector $\mathbf{k}_{1}$ that can chosen to be a probability vector; in this case $\mathbf{k}_{1}$ is the equilibrium probability.

Eigenvalues and eigenvectors:

| $\lambda_{1}=1$ | $\mathbf{k}_{1}=\left[\begin{array}{c}1 \\ \frac{12}{5}\end{array}\right]$ |
| :--- | :--- |
| $\lambda_{2}=\frac{3}{20}$ | $\mathbf{k}_{2}=\left[\begin{array}{c}1 \\ -1\end{array}\right]$ |

Computation Practice

$$
P=\left[\begin{array}{ll}
1 / 3 & 1 / 2 \\
2 / 3 & 1 / 2
\end{array}\right] \quad \mathrm{x}_{0}=\left[\begin{array}{c}
a \\
1-a
\end{array}\right], a \in[0,1]
$$

1. Find all eigenvalues of $P$, and an associated eigenvector to each.
2. Write $\mathbf{x}_{0}$ as a linear combination of eigenvectors of $P$.
3. Calculate $\mathbf{x}_{n}$, where $n$ is some positive integer.
4. Find the equilibrium probability of $P$.
(If this is the only thing we want to find, we can skip all other steps, and simply find the eigenvector associated to eigenvalue 1 , then scale it to be a probability vector.)

## Course Notes 6.2: Eigenanalysis Simplifies Matrix Powers

1. Find Eigenvalues and Eigenvectors

By our theorem, we know that 1 will be an eigenvalue. However, for the sake of practice, let's find them the old-fashioned way.

Eigenvalues of $P$ are precisely those scalars $\lambda$ such that $\operatorname{det}(P-\lambda I)=0$. So we set the determinant equal to zero:
$\operatorname{det}\left[\begin{array}{cc}1 / 3-\lambda & 1 / 2 \\ 2 / 3 & 1 / 2-\lambda\end{array}\right]=\left(\frac{1}{3}-\lambda\right)\left(\frac{1}{2}-\lambda\right)-\left(\frac{1}{2}\right)\left(\frac{2}{3}\right)=\lambda^{2}-\frac{5}{6} \lambda-\frac{1}{6}$
And find $\lambda_{1}=1$ (as expected) and $\lambda_{2}=-\frac{1}{6}$.

To find the associated eigenvectors, we set $P \mathbf{x}=\lambda \mathbf{x}$. (Next Slide)

## Course Notes 6.2. Eigenanalysis Simplifies Matrix Powers

1. Find Eigenvalues and Eigenvectors

$$
\begin{aligned}
& \lambda_{1}=1 \\
& {\left[\begin{array}{ll}
1 / 3 & 1 / 2 \\
2 / 3 & 1 / 2
\end{array}\right]\left[\begin{array}{l}
x \\
y
\end{array}\right]=1\left[\begin{array}{l}
x \\
y
\end{array}\right] \quad \rightarrow \quad\left[\begin{array}{cc}
-2 / 3 & 1 / 2 \\
2 / 3 & -1 / 2
\end{array}\right]\left[\begin{array}{l}
x \\
y
\end{array}\right]=\left[\begin{array}{l}
0 \\
0
\end{array}\right]}
\end{aligned}
$$

The solutions to this system are of the form $s\left[\begin{array}{l}3 \\ 4\end{array}\right]$ for some scalar s. Any vector of this form will do.
$\lambda_{2}=-\frac{1}{6}$

$$
\left[\begin{array}{ll}
1 / 3 & 1 / 2 \\
2 / 3 & 1 / 2
\end{array}\right]\left[\begin{array}{l}
x \\
y
\end{array}\right]=-\frac{1}{6}\left[\begin{array}{l}
x \\
y
\end{array}\right] \quad \rightarrow \quad\left[\begin{array}{ll}
1 / 2 & 1 / 2 \\
2 / 3 & 2 / 3
\end{array}\right]\left[\begin{array}{l}
x \\
y
\end{array}\right]=\left[\begin{array}{l}
0 \\
0
\end{array}\right]
$$

The solutions to this system are of the form $s\left[\begin{array}{c}1 \\ -1\end{array}\right]$ for some scalar s. Any vector of this form will do.

2. Basis Vectors

## Notes

To find $x_{0}$ as a combination of eigenvectors, we have to CHOOSE our eigenvectors. I like integers, so I'll use $\mathbf{k}_{1}=\left[\begin{array}{l}3 \\ 4\end{array}\right]$ and $\mathbf{k}_{2}=\left[\begin{array}{c}1 \\ -1\end{array}\right]$. Your
vectors may be scalar multiples of these.
The equation we have to solve is

$$
\left[\begin{array}{c}
a \\
1-a
\end{array}\right]=x\left[\begin{array}{l}
3 \\
4
\end{array}\right]+y\left[\begin{array}{c}
1 \\
-1
\end{array}\right]
$$

which can be rewritten as

$$
\left[\begin{array}{cc}
3 & 1 \\
4 & -1
\end{array}\right]\left[\begin{array}{l}
x \\
y
\end{array}\right]=\left[\begin{array}{c}
a \\
1
\end{array}-a\right]
$$

Since $a$ is a constant, we can solve this using an augmented matrix and row reduction

$$
\begin{aligned}
& {\left[\begin{array}{cc|c}
3 & 1 & a \\
4 & -1 & 1-a
\end{array}\right] \xrightarrow{R_{2} \rightarrow R_{2}+R_{1}}\left[\begin{array}{ll|l}
3 & 1 & a \\
7 & 0 & 1
\end{array}\right]} \\
& \text { So } x=\frac{1}{7} \text { and } y=a-\frac{3}{7} \text {. That is, } \mathbf{x}_{0}=\frac{1}{7} \mathbf{k}_{1}+\left(a-\frac{3}{7}\right) \mathbf{k}_{2} .
\end{aligned}
$$

## Course Notes 6.2: Eigenanalysis Simplifies Matrix Powers

3. Find $\mathrm{x}_{n}$

Recall $\mathbf{x}_{n}=P^{n} \mathbf{x}_{0}$. With our previous work, the answer is an easy calculation.

$$
\begin{aligned}
\mathbf{x}_{n} & =P^{n} \mathbf{x}_{0}=P^{n}\left(\frac{1}{7} \mathbf{k}_{1}+\left(\frac{3}{7}-a\right) \mathbf{k}_{2}\right) \\
& =\frac{1}{7} P^{n} \mathbf{k}_{1}+\left(\frac{3}{7}-a\right) P^{n} \mathbf{k}_{\mathbf{2}} \\
& =\frac{1}{7} \mathbf{k}_{\mathbf{1}}+\left(\frac{3}{7}-a\right)\left(-\frac{1}{6}\right)^{n} \mathbf{k}_{\mathbf{2}} \\
& =\left[\begin{array}{l}
\frac{3}{7} \\
\frac{4}{7}
\end{array}\right]+\left[\begin{array}{c}
\left(\frac{3}{7}-a\right)(-1 / 6)^{n} \\
-\left(\frac{3}{7}-a\right)(-1 / 6)^{n}
\end{array}\right] \\
& =\left[\begin{array}{l}
\frac{3}{3}+\left(\frac{3}{3}-a\right)(-1 / 6)^{n} \\
\frac{4}{7}-\left(\frac{3}{7}-a\right)(-1 / 6)^{n}
\end{array}\right]
\end{aligned}
$$

## Course Notes 6 .2: Eigenanalysis Simplifies Matrix Powers

4. Find the Equilibrium Probability

Recall the equilibrium probability is $\lim \mathrm{x}_{n}=\lim P^{n} \mathrm{x}_{0}$. With our previous work, the answer is an easy calculation. Using an intermediate result from the last slide:

$$
\begin{aligned}
\lim _{n \rightarrow \infty} \mathbf{x}_{n} & =\lim _{n \rightarrow \infty}\left[\frac{1}{7} \mathbf{k}_{1}+\left(\frac{3}{7}-a\right)\left(-\frac{1}{6}\right)^{n} \mathbf{k}_{2}\right] \\
& =\frac{1}{7} \mathbf{k}_{1} \\
& =\left[\begin{array}{l}
\frac{3}{7} \\
4 \\
7
\end{array}\right]
\end{aligned}
$$

## Notes

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$ probability will alw eigenvalue $\lambda=1$. Since our eigenvectors were of the form $s[3,4]$, we can find the equilibrium probability by figuring out which value of $s$ gives us a vector whose entries sum to one; $s=7$ is that scalar.

Complex Eigenvalues: A Neat Trick

$$
\begin{gathered}
A=\left[\begin{array}{cc}
0 & 1 \\
-1 & 0
\end{array}\right] \quad \mathbf{x}=\left[\begin{array}{l}
2 \\
3
\end{array}\right] \\
\lambda_{1}=i, \mathbf{k}_{1}=\left[\begin{array}{c}
-i \\
1
\end{array}\right] \quad \lambda_{2}=-i, \mathbf{k}_{2}=\left[\begin{array}{c}
i \\
1
\end{array}\right]
\end{gathered}
$$

If the entries of $A$ are all real, its eigenvalues and eigenvectors are complex conjugates of one another.

## Course Notes $6.2:$ Eigenanalysis Simplifies Matrix Powers 00000000000000000 <br> Complex Eigenvalues: A Neat Trick <br> $A \mathbf{x}=\lambda \mathbf{x}$ Definition: $\lambda, \mathbf{x}$ are an eigenvalue-eigenvector pair of $A$ <br> $\overline{A \mathbf{x}}=\overline{\lambda \mathbf{x}}$ Take the conjugate of each entry <br> $\bar{A} \bar{x}=\bar{\lambda} \bar{x}$ conjugation distributes over multiplication <br> $A \overline{\mathrm{x}}=\bar{\lambda} \overline{\mathrm{x}}$ If $A$ has only real entries, then $\bar{A}=A$.

Definition: $\bar{\lambda}, \overline{\mathbf{x}}$ are an eigenvalue-eigenvector pair of $A$
(If $\lambda$ and $\mathbf{x}$ are real-valued, this statement is true but not interesting, because $\bar{\lambda}=\lambda$ and $\overline{\mathbf{x}}=\mathbf{x}$.)

Suppose $A$ is a 3 -by- 3 matrix with all real entries, whose eigenvectors form a basis of $\mathbb{R}^{3}$.

- If $A$ has eigenvalue-eigenvector pair $\lambda=(2+i), \mathbf{k}=\left[\begin{array}{c}3 i+4 \\ 2 i-9\end{array}\right]$, give another eigenvalue-eigenvector pair
- If $\lambda_{1}=1$ and $\lambda_{2}=5+4 i$, what is $\lambda_{3}$ ?
- If $A$ has eigenvalue-eigenvector pair $\lambda=5+\sqrt{-2}$, $\mathbf{k}=\left[\begin{array}{c}3 \\ 18+\sqrt{-3}\end{array}\right]$, give another eigenvalue-eigenvector pair.

## Course Notes 6.2: Eigenanalysis Simplifies Matrix Powers <br> Complex Eigenvalues

Find all eigenvalues and eigenvectors of :

$$
A=\left[\begin{array}{cc}
-3 & 5 \\
-2 & -1
\end{array}\right]
$$

## Course Notes 6.2: Eigenanalysit 000000000000000000000

Eigenfact or Eigenfiction?

Let $A$ be a matrix with eigenvalue $\lambda$ and associated eigenvector $\mathbf{k}$.
True or False:

1. $2 \mathbf{k}$ is an eigenvector of $A$, associated with $\lambda$.
2. It is possible that $\mathbf{k}$ is an eigenvalue of $A$ associated with a different eigenvalue (that is, other than $\lambda$ ).
3. All eigenvectors of $A$ associated with $\lambda$ are scalar multiples of k.
4. $\mathbf{k}$ might be the zero vector.
5. $\lambda$ might be zero.
6. If $A$ has only real entries, then $\lambda$ is real.
7. If $A$ has only real entries, and $\mathbf{k}$ has only real entries, then $\lambda$ is real.

## Notes

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

Explanations

1. Check the definition of eigenvalues and eigenvectors:

$$
A \mathbf{k}=\lambda \mathbf{k} \Longrightarrow 2 A \mathbf{k}=2 \lambda \mathbf{k} \Longrightarrow A(2 \mathbf{k})=\lambda(2 \mathbf{k})
$$

Indeed, any nonzero multiple of $\mathbf{k}$ is an eigenvector of $A$, associated with $\lambda$.
2. $\mathbf{k}$ is not the zero vector, so it has some nonzero entry, say
$\mathbf{k}=\left[k_{1}, k_{2}, \ldots, k_{n}\right]^{T}$ and $k_{i} \neq 0$. If $\lambda$ and $\gamma$ are both eigenvalues associated with $\mathbf{k}$, then:

$$
\lambda \mathbf{k}=A \mathbf{k}=\gamma \mathbf{k} \Longrightarrow \lambda \mathbf{k}=\gamma \mathbf{k}
$$

so, in particular, $\lambda k_{i}=\gamma k_{i}$; since $k_{i} \neq 0$, this implies $\lambda=\gamma$. That is, the two eigenvalues were actually the same.

## Course Notes 6.2: Eigenanayysis Simplifies Matrix Powers <br> Explanations

3. Consider $A=I_{2}$ (the $2 \times 2$ identity matrix), $\lambda=1, \mathbf{k}_{1}=[1,0]^{T}$ and $\mathbf{k}_{2}=[0,1]^{T}$.
4. By definition, eigenvectors are nonzero.
5. For example, $A=\left[\begin{array}{ll}0 & 1 \\ 0 & 1\end{array}\right], \lambda=0$, and $\mathbf{k}=[10]^{T}$.
6. We've seen several examples of real-valued matrices with complex eigenvalues

## Notes

7. If $A$ and $\mathbf{k}$ are real-valued, then $A k$ has only real entries as well. Therefore, $\lambda \mathbf{k}$ has only real entries. If $\lambda$ isn't real, then the entries of $\lambda \mathbf{k}$ contain at least one nonzero entry, and this entry isn't real because it's a nonreal complex number multiplied by a nonzero real number. This is a contradiction.
