Linear Regression

Imagine an experiment in which you measure one quantity, call it y, as a function of a second quantity, say x. For example, y could be the current that flows through a resistor when a voltage x is applied to it. Suppose that you measure n data points $(x_1, y_1), \dots, (x_n, y_n)$ and that you wish to find the straight line y = mx + b that fits the data best. If the data point

 (x_i, y_i) were to land exactly on the line y = mx + b we would have $y_i = mx_i + b$. If it doesn't land exactly on the line, the vertical distance between (x_i, y_i) and the line y = mx + b is $|y_i - mx_i - b|$. That is the discrepancy between the measured value of y_i and the corresponding idealized value on the line is $|y_i - mx_i - b|$. One measure of the total discrepancy for all data points is $\sum_{i=1}^{n} |y_i - mx_i - b|$. A more convenient measure, which avoids the absolute value signs, is

$$D(m,b) = \sum_{i=1}^{n} (y_i - mx_i - b)^2$$

We will now find the values of m and b that give the minimum value of D(m, b). The corresponding line y = mx + b is generally viewed as the line that fits the data best.

You learned in your first Calculus course that the value of m that gives the minimum value of a function of one variable f(m) obeys f'(m) = 0. The analogous statement for functions of two variables is the following. First pretend that b is just a constant and compute the derivative of D(m,b) with respect to m. This is called the partial derivative of D(m,b) with respect to m and denoted $\frac{\partial D}{\partial m}(m,b)$. Next pretend that m is just a constant and compute the derivative of D(m,b) with respect to m. This is called the partial derivative of m0 with respect to m1. If m2 gives the minimum value of m3, then

$$\frac{\partial D}{\partial m}(m,b) = \frac{\partial D}{\partial b}(m,b) = 0$$

For our specific D(m, b)

$$\frac{\partial D}{\partial m}(m,b) = \sum_{i=1}^{n} 2(y_i - mx_i - b)(-x_i)$$

$$\frac{\partial D}{\partial b}(m,b) = \sum_{i=1}^{n} 2(y_i - mx_i - b)(-1)$$

It is important to remember here that all of the x_i 's and y_i 's here are given numbers. The only unknowns are m and b. The two partials are of the forms

$$\frac{\partial D}{\partial m}(m,b) = 2c_{xx}m + 2c_xb - 2c_{xy}$$
$$\frac{\partial D}{\partial b}(m,b) = 2c_xm + 2nb - 2c_y$$

where the various c's are just given numbers whose values are

$$c_{xx} = \sum_{i=1}^{n} x_i^2$$
 $c_x = \sum_{i=1}^{n} x_i$ $c_{xy} = \sum_{i=1}^{n} x_i y_i$ $c_y = \sum_{i=1}^{n} y_i$

So the value of (m, b) that gives the minimum value of D(m, b) is determined by

$$c_{xx}m + c_xb = c_{xy} \qquad (1)$$

$$c_x m + nb = c_y \tag{2}$$

This is a system of two linear equations in the two unknowns m and b, which is easy to solve:

$$n(1) - c_x(2) : [nc_{xx} - c_x^2]m = nc_{xy} - c_x c_y \implies m = \frac{nc_{xy} - c_x c_y}{nc_{xx} - c_x^2}$$

$$c_x(1) - c_{xx}(2) : [c_x^2 - nc_{xx}]b = c_x c_{xy} - c_{xx} c_y \implies b = \frac{c_{xx} c_y - c_x c_{xy}}{nc_{xx} - c_x^2}$$
