1. (a) Evaluate $\lim_{(x,y)\to(1,-1)} \frac{\sin(x^2+y)}{x^2+y}$ or show that it doesn't exist. We can use the substitution $u = x^2 + y$, so $u \to 1^2 - 1 = 0$:

$$\lim_{(x,y)\to(1,-1)}\frac{\sin(x^2+y)}{x^2+y} = \lim_{u\to 0}\frac{\sin(u)}{u} = \lim_{u\to 0}\frac{\sin(u)-\sin(0)}{u-0} = \frac{d}{dt}\sin(t)\Big|_{t=0} = \cos(0) = \boxed{1}.$$

Here we used the definition of derivative, $f'(a) = \lim_{x \to a} \frac{f(x) - f(a)}{x - a}$, in reverse.

(b) Consider the area function $A(x) = \int_1^x f(t)dt$, with A(2) = 6 and A(3) = 5. Compute $\int_3^2 f(t)dt$.

By the Fundamental Theorem of Calculus, $\int_{3}^{2} f(t)dt = A(2) - A(3) = 6 - 5 = \boxed{1}$.

(c) A self-employed software engineer estimates that her annual income over the next 10 years will steadily increase according to the formula 70,000e^{0.1t}, where t is the time in years. She decides to save 10% of her income in an account paying 6% annual interest, compounded continuously. Treating the savings as a continuous income stream over a 10-year period, find the present value.

$$PV = \int_0^{10} 7000e^{0.1t}e^{-0.06t}dt = 7000 \int_0^{10} e^{0.04t}dt = 7000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} \Big|_0^{10} = \boxed{175000(e^{0.4} - 1)} (\approx 86,000) + 1000 \cdot \frac{1}{0.04} e^{0.04t} = 1000 \cdot \frac{1}{0.04} e^{$$

(d) Draw the level curves of the graph of $f(x, y) = 2x^2 + y^2$ at the heights 0, 1, 2. For 1 and 2 it's an ellipse, for 0 it's just the point (0, 0).

(e) Evaluate
$$\int_{0}^{1} \frac{\cos(\sqrt{x})}{\sqrt{x}} dx$$
.
 $\int \frac{\cos(\sqrt{x})}{\sqrt{x}} dx \stackrel{u=\sqrt{x}}{=} 2 \int \cos(u) du = 2\sin(u) + C = 2\sin(\sqrt{x}) + C,$
 $\int_{0}^{1} \frac{\cos(\sqrt{x})}{\sqrt{x}} dx = 2 \lim_{c \to 0^{+}} \sin(\sqrt{x}) \Big|_{c}^{1} = 2 \lim_{c \to 0^{+}} (\sin(1) - \sin(c)) = 2(\sin(1) - \sin(0)) = 2(\sin(1) - \sin(1) - \sin(1)) = 2(\sin(1) - \sin(1)) = 2$

(f) Let
$$f(x,y) = \frac{x+y}{x-y}$$
. Use linear approximation to estimate $f(2.95, 2.05)$.

$$f_x = \frac{-2y}{(x-y)^2}, \qquad f_y = \frac{2x}{(x-y)^2}$$
$$dz = f_x(3,2)dx + f_y(3,2)dy = (-4) \cdot (-0.05) + 6 \cdot 0.05 = 0.5$$
$$\Rightarrow \quad f(2.95,2.05) \approx f(3,2) + dz = 5 + 0.5 = \boxed{5.5}$$

2. Evaluate $\int \frac{x+2}{x(x^2-1)} dx$. = $-2 \int \frac{1}{x} dx + \frac{3}{2} \int \frac{1}{x-1} dx + \frac{1}{2} \int \frac{1}{x+1} dx = \boxed{-2\ln|x| + \frac{3}{2}\ln|x-1| + \frac{1}{2}\ln|x+1| + C}$ 3. Find the area of the region in the first quadrant bounded by $y = \frac{1}{x}$, y = 4x, and $y = \frac{1}{2}x$.

$$= \int_{0}^{1/2} (4x - \frac{1}{2}x)dx + \int_{1/2}^{\sqrt{2}} (x^{-1} - \frac{1}{2}x)dx = \frac{7}{4}x^{2}\Big|_{0}^{1/2} + (\ln|x| - \frac{1}{4}x^{2})\Big|_{1/2}^{\sqrt{2}}$$
$$= \frac{7}{16} + \ln(\sqrt{2}) - \frac{1}{2} - \ln(1/2) + \frac{1}{16} = \boxed{\frac{3}{2}\ln(2)}$$

4. Find k such that $f(x) = \frac{k}{(x+1)^3}$ is a probability density function on the interval $[0, \infty)$. Then compute the probability that $1 \le x \le 4$.

$$1 = \int_0^\infty \frac{k}{(x+1)^3} dx = k \lim_{c \to \infty} -\frac{1}{2} (x+1)^{-2} \Big|_0^c = \frac{k}{2} \lim_{c \to \infty} \left(1 - \frac{1}{(c+1)^2} \right) = \frac{k}{2} \implies \boxed{k=2}$$
$$\Pr(1 \le X \le 4) = \int_1^4 \frac{2}{(x+1)^3} dx = -(x+1)^{-2} \Big|_1^4 = \frac{1}{4} - \frac{1}{25} = \frac{21}{100}$$

5. Mothballs tend to evaporate at a rate proportional to their surface area. If V is the volume of a mothball, then its surface area is roughly V^{2/3}. Suppose that the mothball's volume V(t) (as a function of times t in weeks) decreases at a rate that is twice its surface area, and that it initially has a volume of 27 cubic centimeters. Construct and solve an initial value problem for the volume V(t). Then determine if and when the mothball vanishes.

$$\frac{dV}{dt} = -2V^{2/3} \Rightarrow \int V^{-2/3} dV = \int -2dt \Rightarrow 3V^{1/3} = -2t + C_1 \Rightarrow V = \left(-\frac{2}{3}t + C_2\right)^3$$
$$27 = V(0) = C_2^3 \Rightarrow C_2 = 3 \Rightarrow V(t) = \left(3 - \frac{2}{3}t\right)^3, \quad V(t) = 0 \Rightarrow t = \frac{9}{2}$$

6. Consider the surface $z = f(x, y) = 1 + \frac{1}{\sqrt{xy}}$. At the point on the surface above the point (x, y) = (4, 1), what is the direction of steepest descent? Describe this direction with a unit vector in the xy-plane.

$$\begin{split} \nabla f &= \left\langle -\frac{1}{2x^{3/2}y^{1/2}}, -\frac{1}{2x^{1/2}y^{3/2}} \right\rangle \implies \nabla f = \left\langle -\frac{1}{16}, -\frac{1}{4} \right\rangle \\ \text{length} &= \sqrt{\left(-\frac{1}{16}\right)^2 + \left(-\frac{1}{4}\right)^2} = \sqrt{\frac{4^2 + 1}{16^2}} = \frac{\sqrt{17}}{16} \\ \Rightarrow \text{ unit vector of steepest descent } &= -\frac{1}{\sqrt{17}/16} \left\langle -\frac{1}{16}, -\frac{1}{4} \right\rangle = \boxed{\left\langle \frac{1}{\sqrt{17}}, \frac{4}{\sqrt{17}} \right\rangle} \end{split}$$

7. By employing x semi-skilled workers and y skilled workers, a factory can assemble $\sqrt{4xy + y^2}$ custom-built computers per hour. The factory pays each semi-skilled worker \$8 per hour, and each skilled worker \$20 per hour. Determine the maximum number of computers the factory can assemble in an hour for a total labour cost of \$720.

optimize
$$f(x,y) = \sqrt{4xy + y^2}$$
 subject to $g(x,y) = 8x + 20y - 720 = 0$
 $\Rightarrow \nabla f = \left\langle \frac{2y}{\sqrt{4xy + y^2}}, \frac{2x + y}{\sqrt{4xy + y^2}} \right\rangle, \quad \nabla g = \langle 8, 20 \rangle$

 $\Rightarrow \text{ equations to solve:} \quad \frac{2y}{\sqrt{4xy+y^2}} = 8\lambda, \quad \frac{2x+y}{\sqrt{4xy+y^2}} = 20\lambda, \quad 8x+20y = 720$

$$\Rightarrow \text{ eliminate } \lambda: \ \lambda = \frac{y}{4\sqrt{4xy + y^2}} = \frac{2x + y}{20\sqrt{4xy + y^2}} \Rightarrow \ \frac{y}{4} = \frac{2x + y}{20} \Rightarrow \ y = \frac{1}{2}x$$

 \Rightarrow plug into constraint: $720 = 8x + 20 \cdot \frac{1}{2}x = 18x \Rightarrow x = 40 \Rightarrow y = 20$

To see if this is a max or a min, we take an arbitrary other point satisfying the constraint, like (0, 36), and compare the values: f(0, 36) = 36 while $f(40, 20) = \sqrt{3200 + 400} = 60$, so the maximum number of computers is 60.

Note: Since the question did not specifically ask for Lagrange Multipliers, this question could have been done with one-variable calculus.

A trick to make things easier is to optimize f^2 instead of f, which will give the same x and y.

8. Find and classify the critical points of $f(x, y) = 7x^2 - 5xy + y^2 + x - y + 6$.

$$\begin{aligned} f_x &= 14x - 5y + 1 = 0, \quad f_y = -5x + 2y - 1 = 0\\ \Rightarrow & y = \frac{14x + 1}{5} \Rightarrow 0 = -5x + 2 \cdot \frac{14x + 1}{5} - 1 = -5x + \frac{28}{5}x + \frac{2}{5} - 1 = \frac{3}{5}x - \frac{3}{5}\\ \Rightarrow & x = 1, \quad y = 3 \quad \Rightarrow \quad \boxed{(1,3) \text{ is the only critical point}}\\ f_{xx} &= 14, \quad f_{yy} = 2, \quad f_{xy} = -5 \quad \Rightarrow \quad D(x,y) = 28 - (-5)^2 = 3\\ D(1,3) &= 3 > 0, \quad f_{xx}(1,3) = 14 > 0 \quad \Rightarrow \quad \boxed{(1,3) \text{ is a minimum}}\end{aligned}$$

9. Given the supply and demand curves

$$p = D(q) = 8 - q,$$
 $p = S(q) = \sqrt{q+1} + 3,$

find the equilibrium point and the consumer/producer surplus.

$$\sqrt{q+1}+3 = 8-q \implies q+1 = (5-q)^2 = 25-10q+q^2 \implies 0 = q^2-11q+24 = (q-3)(q-8)$$
$$\implies q_e = 3, p_e = 5$$

Note that q = 8 is not a solution, since $\sqrt{8+1}+3 \neq 8-8$. Look at the graph: q = 8 is where the line intersects the graph of $-\sqrt{q+1}+3$, which shows up because we squared both sides of the equation while solving.

$$CS = \int_0^3 (8-q)dq - 3 \cdot 5 = 24 - \frac{9}{2} - 15 = \boxed{\frac{9}{2}}$$
$$PS = 3 \cdot 5 - \int_0^3 (\sqrt{q+1}+3)dq = 15 - \left(\frac{2}{3}(q+1)^{3/2} + 3q\right)\Big|_0^3 = 15 - \frac{16}{3} - 9 + \frac{2}{3} = \boxed{\frac{4}{3}}$$
