## NOTE

# Polygon Dissections and Standard Young Tableaux

A simple bijection is given between dissections of a convex $(n+2)$-gon with $d$ diagonals not intersecting in their interiors and standard Young tableaux of shape $\left(d+1, d+1,1^{n-1-d}\right)$. © 1996 Academic Press, Inc.

For $0 \leqslant d \leqslant n-1$, let $f(n, d)$ be the number of ways to draw $d$ diagonals in a convex $(n+2)$-gon, such that no two diagonals intersect in their interior. For instance, $f(n, n-1)$ is just the Catalan number $C_{n}=\binom{2 n}{n} /(n+1)$. A result going back to Kirkman [3], Prouhet [4], and Cayley [1] (with Cayley giving the first complete proof) asserts that

$$
\begin{equation*}
f(n, d)=\frac{1}{n+d+2}\binom{n+d+2}{d+1}\binom{n-1}{d} \tag{1}
\end{equation*}
$$

K. O'Hara and A. Zelevinsky observed (unpublished) that the right-hand side of (1) is just the number of standard Young tableaux (as defined, e.g., in $[5, \mathrm{p} .66]$ ) of shape $\left(d+1, d+1,1^{n-1-d}\right)$, where $1^{n-1-d}$ denotes a sequence of $n-1-d$ l's. It is natural to ask for a bijection between the polygon dissections and the standard Young tableaux. If one is willing to accept the formula for the number of standard Young tableaux of a fixed shape (either in the original form due to MacMahon or the hook-length formula of Frame-Robinson-Thrall), then one obtains a simple proof

[^0]of equation (1). In this note we give a simple bijection of the desired type.

First we recall that there is a well-known bijection [2] between dissections $D$ of an $(n+2)$-gon with $d$ diagonals and integer sequences $\psi(D)=\left(a_{1}, a_{2}, \ldots, a_{n+d+1}\right)$ such that (a) either $a_{i}=-1$ or $a_{i} \geqslant 1$, (b) exactly $n$ terms are equal to -1 , (c) $a_{1}+a_{2}+\cdots+a_{i} \geqslant 0$ for all $i$, and (d) $a_{1}+a_{2}+\cdots+a_{n+d+1}=0$. This bijection may be defined recursively as follows. Fix an edge $e$ of the dissected polygon $D$. When we remove $e$ from $D$, we obtain a sequence of dissected polygons $D_{1}, D_{2}, \ldots, D_{k}$ (where $k+1$ is the number of sides of the region of $D$ to which $e$ belongs), arranged in clockwise order, with $D_{i}$ and $D_{i+1}$ intersecting at a single vertex. If $D_{i}$ consists of a single edge, then define $\psi\left(D_{i}\right)=-1$, and set recursively $\psi(D)=\left(k-1, \psi\left(D_{1}\right)^{*}, \psi\left(D_{2}\right)^{*}, \ldots, \psi\left(D_{k-1}\right)^{*}, \psi\left(D_{k}\right)\right)$, where $\psi\left(D_{k}\right) *$ denotes $\psi\left(D_{k}\right)$ with a -1 appended at the end.

Given a sequence $\left(a_{1}, a_{2}, \ldots, a_{n+d+1}\right)$ as above, define a standard Young tableau $T$ of shape $\left(d+1, d+1,1^{n-1-d}\right)$ as follows. We insert the elements $1,2, \ldots, n+d+1$ successively into $T$. Once an element is inserted, it remains in place. (There is no "bumping" as in the Robinson-Schensted correspondence.) Suppose that the positive $a_{i}$ 's are given by $b_{1}, b_{2}, \ldots, b_{d+1}$, in that order. The insertion is then defined by the following three rules:

- If $a_{i}>0$, then insert $i$ at the end of the first row. (We write our tableaux in "English" style, so the longest row is at the top.)
- If $a_{i}=-1$ and the number of -1 's preceding $a_{i}$ is given by $b_{1}+b_{2}+\cdots+b_{j}$ for some $j \geqslant 0$, then insert $i$ at the end of the second row.
- If $a_{i}=-1$ and the number of -1 's preceding $a_{i}$ in not of the form $b_{1}+b_{2}+\cdots+b_{j}$, then insert $i$ at the bottom of the first column.

It is an easy exercise to check that the above procedure yields the desired bijection.

Example. Let the sequence corresponding to a dissection $D$ (with $n=14, d=6$ ) be given by

$$
\begin{aligned}
& (4,2,-\mathbf{1}, 1,-1,-1,3,-1,-\mathbf{1}, 1,1,-1,-\mathbf{1},-\mathbf{1}, \\
& \quad-1,-1,-\mathbf{1}, 2,-\mathbf{1},-\mathbf{1},-1)
\end{aligned}
$$

We have $\left(b_{1}, \ldots, b_{7}\right)=(4,2,1,3,1,1,2)$. We have printed in boldface those -1 's that are preceded by $b_{1}+\cdots+b_{j}-1$ 's for some $j$. The corresponding standard tableau $\psi(D)$ is given by

| 1 | 2 | 4 | 7 | 10 | 11 | 18 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 3 | 9 | 13 | 14 | 17 | 19 | 20 |
| 5 |  |  |  |  |  |  |
| 6 |  |  |  |  |  |  |
| 8 |  |  |  |  |  |  |
| 12 |  |  |  |  |  |  |
| 15 |  |  |  |  |  |  |
| 16 |  |  |  |  |  |  |
| 21 |  |  |  |  |  |  |
