Compact operators

This is a sequel to an introductory essay on Hilbert spaces. It deals specifically with compact operators and, for the most part, follows [Reed-Simon:1972]. The only unusual feature is the exposition of the theorem in [Duflo:1972] concerning the trace of integral operators as an integral over the diagonal. This is a basic result, frequently referred to without clear justification. Duflo’s own account, as pointed out to me by Chris Brislawn, contains several confusing small errors.

The most satisfactory current account of this theorem is probably that in [Brislawn:1991], but it involves a number of techniques I am not familiar with (primarily, the application of martingales to analysis).

Contents

All Hilbert spaces in this essay are assumed to be separable, which means they possess countable orthonormal bases.

1. Compact operators

An operator $T: H_1 \to H_2$ is said to be of **finite rank** if its image has finite dimension. The simplest such map has rank one, and is of the form

$$u \otimes v: w \mapsto (w \cdot v)u \quad (v \in H_1, u \in H_2).$$

Any map of finite rank is a sum of maps of rank one, and if we apply the singular value decomposition we may put it in a special form. Suppose $T: H \to U$ to be a continuous linear map of finite rank, with $T = U|T|$ ($U$ unitary). Here $|T|$ is a positive, bounded, self-adjoint operator of finite rank. Its kernel is the same as $K = \text{Ker}(T)$, and takes the orthogonal complement $K^\perp$ of $K$ to itself. This space is finite-dimensional, and hence there exists an orthonormal basis $\{v_i\}$ of $K$ and eigenvalues $\lambda_i > 0$ such that $T(v_i) = \lambda_i v_i$. If $u_i = U(v_i)$, the $u_i$ form an orthonormal set in $H_2$ and

$$T: w \mapsto \sum \lambda_i (w \cdot v_i)u_i.$$

Now suppose $\{\lambda_i\}$ to be an infinite bounded sequence of complex numbers, $\{u_i\}$ to be an orthonormal subset of $H_1$, $\{v_i\}$ to be one of $H_1$. Then the formula

$$T: w \mapsto \sum \lambda_i (w \cdot v_i)u_i$$
defines a bounded operator from $H_1$ to $H_2$, with bound equal to $\lim \sup |\lambda_i|$. We can read off the singular value decomposition easily since

$$|T|(w) = \sum |\lambda_i|(w \cdot v_i)v_i,$$

with the $|\lambda_i|$ its eigenvalues.

There is an important difference between sequences $\lambda_i$ that converge to 0 and those that do not. It is those in the first group that this essay is concerned with. What is the difference, exactly? Simplify things slightly by assuming the $\lambda_i$ to be a decreasing positive real sequence. If $T_n$ is the operator

$$T_n: v = \sum c_i v_i \mapsto \sum_{i \leq n} c_i \lambda_i v_i$$

then

$$\|T(v) - T_n(v)\|^2 \leq \lambda_{n+1}^2 \left( \sum_{i > n} |c_i|^2 \right) \leq \lambda_{n+1}^2 \|v\|^2$$

so that $\|T - T_n\| \leq \lambda_{n+1}$. Therefore if $\lambda_n \to 0$ the operator $T$ is the limit in the norm topology of the operators $T_n$, all of which have finite rank.

The operators that possess this property are quite special. A bounded operator $T$ from one Hilbert space to another is called compact (for reasons that will become apparent in a moment) if for every $\varepsilon > 0$ there exists an operator $F$ of finite rank such that $\|T - F\| < \varepsilon$. The following is immediate:

**1.1. Proposition.** The subspace of compact operators is closed in the space of all bounded operators.

**WHY ARE THEY CALLED COMPACT?** There is another useful way to characterize such operators, which explains the terminology.

**1.2. Theorem.** A bounded linear operator is compact if and only if it takes bounded subsets into relatively compact ones.

I recall that a set is called relatively compact if its closure is compact.

The proof requires a preliminary discussion of compactness. Let $X$ be an arbitrary complete separable metric space. (Separability means there exists a countable dense subset.) The classic theorem of Heine-Borel asserts that there are two equivalent definitions of compactness of a subset $K$ of $X$: (1) every covering of $K$ by open sets possesses a finite sub-covering; (2) every sequence of points in $K$ contains a subsequence of points converging to a point in $K$. Compact sets are closed. A set is called totally bounded if for any $\varepsilon > 0$ it may be covered by a finite set of $\varepsilon$-balls.

**1.3. Proposition.** If $X$ is a complete separable metric space, the following are equivalent conditions on a subset $K$ of $X$:

(a) every sequence of points in $K$ contains a subsequence that converges to a point of $X$;

(b) the subset $K$ is relatively compact;

(c) the subset $K$ is totally bounded.

**Proof.** (a) implies (b): Let $y_i$ be a sequence of points in $\overline{K}$. For each of these, let $x_i$ be a point of $K$ such that $|x_i - y_i| \leq 1/i$. By assumption, there exists a subsequence $x_{i_j}$ converging to some $y$ in $X$. The subsequence $y_{i_j}$ converges to the same point.

(b) implies (c): Immediate.

(c) implies (a): Let $x_i$ be any sequence of points in $K$. The set $K$ can be covered by a finite number of balls of radius 1, so one of them must contain an infinite subsequence of them. And so on for balls of radius $1/n$ for all $n > 1$. In this way we get a Cauchy subsequence in $K$.

The last part of the proof uses the Axiom of Choice.
Let

1.4. Proposition. The following is a classic result.

One important thing about the first assertion is that the poles of ideas of what happens by looking at finite matrices in Jordan form. I’ll mention here is that $T$ is stable. One can deduce the nature of this filtration from the nature of the pole of $\mathcal{F}$, and we also know that there exists $x_i$ with

$$\|F(v) - x_i\| \leq \varepsilon/2.$$  

But then

$$\|T(v) - x_i\| \leq \varepsilon$$

and hence $T(X)$ is covered by the balls $B_{\varepsilon}(x_i)$.

Conversely, suppose that the image of $B_1$ is relatively compact in $H_2$. Given $\varepsilon > 0$, the image $T(B_1)$ may be covered by a finite collection of balls $B_{\varepsilon/2}(x_i)$ for $i = 0, \ldots, n$. Let $\Pi$ be orthogonal projection onto the space spanned by the $x_i$, and $F$ the composition of $T$ followed by $\Pi$. If $v$ lies in $B_1$ then there exists $x_i$ such that $\|T(v) - x_i\| \leq \varepsilon/2$. Since orthogonal projection does not increase lengths

$$\|T(v) - x_i\| \leq \varepsilon/2$$

$$\|\Pi(T(v)) - x_i\| = \|\Pi(T(v)) - \Pi(x_i)\| \leq \varepsilon/2$$

$$\|\Pi(T(v)) - T(v)\| \leq \|\Pi(T(v)) - x_i\| + \|x_i - T(v)\| \leq \varepsilon.$$

Fredholm Theory. Let $H$ be a Hilbert space, $\mathcal{L}(H)$ the ring of bounded operators in $H$. Suppose $D$ to be an open subset of $\mathbb{C}$, $F(z)$ a function on $D$ with values in the space $\mathcal{L}(H)$. It is called analytic if it may be locally expanded in power series converging in the norm topology.

The following is a classic result.

1.4. Proposition. If $T$ is a compact operator from a Hilbert space $H$ to itself, the operator $(I - zT)^{-1}$ is a meromorphic function of $z$ whose poles are the inverses of the non-zero eigenvalues of $T$. For each $\lambda \neq 0$ the subspace $H_\lambda$ of vectors annihilated by some power of $(T - \lambda I)$ has finite dimension.

This last means that the filtration

$$\ker(T - \lambda I) \subseteq \ker(T - \lambda I)^2 \subseteq \ker(T - \lambda I)^3 \subseteq \ldots$$

is stable. One can deduce the nature of this filtration from the nature of the pole of $(I - zT)^{-1}$ at $1/\lambda$, but all I’ll mention here is that $T$ acts as a scalar on this space if and only if the pole is simple. You can get a good idea of what happens by looking at finite matrices in Jordan form.

One important thing about the first assertion is that the poles of $(I - zT)^{-1}$ have no accumulation point in $\mathbb{C}$.

Proof of the Proposition 1.4. Suppose $T$ to be an arbitrary compact operator, and let $C(z) = zT$. Suppose for the moment $z_0$ to be any point of $\mathbb{C}$. Choose $r$ such that $\|C(z) - C(z_0)\| < 1/2$ if $|z - z_0| < r$, and choose an operator $F_0$ of finite rank such that $\|C(z) - F_0\| < 1/2$. Set $\Delta(z) = C(z) - F_0$. Then $\|\Delta(z)\| < 1$ for $|z - z_0| < r$ and in that disc the operator $I + \Delta(z)$ is invertible since the series

$$I + \Delta(z) + \Delta(z)^2 + \cdots$$
converges.

Now
\[ I - C(z) = I - (C(z) - F_0) - F_0 \]
\[ = I - \Delta(z) - F_0 \]
\[ = (I - F_0)(I - \Delta(z))^{-1}(I - \Delta(z)) \]
\[ = (I - G(z))(I - \Delta(z)) \]

where
\[ G(z) = F_0(I - \Delta(z))^{-1} \].

We now require a Lemma.

1.5. Lemma. Suppose \( \varphi(z) \) to be a holomorphic family of bounded operators defined on the open region \( D \subseteq \mathbb{C} \). Suppose \( F \) to be an operator of finite rank, and set
\[ E(z) = F(\varphi(z)) \).

Suppose that there does not exist a vector \( v \neq 0 \) fixed by all \( E(z) \). Then the operator \((I - E(z))^{-1}\) is meromorphic on \( D \) and its poles are at the values of \( z \) for which \( E(z) \) has a non-trivial fixed vector. For any \( z \), the dimension of the space of vectors annihilated by some power of \( I - E(z) \) is finite.

Proof. Suppose that the image of \( F \) is contained in the finite dimensional space \( U \). Let \( u_1, \ldots, u_n \) be an orthonormal basis of \( U \), and extend it to an orthonormal basis \( (u_i) \) of \( H \). Since \( F \) has finite rank, we have
\[ F = \sum u_i \otimes v_i \]
with
\[ [u \otimes v](w) = (w \cdot v) u \].

Then
\[ [E(z)](w) = F([\varphi(z)](w)) = \sum (([\varphi(z)](w) \cdot v_i) u_i = \sum (w \cdot [\varphi(z)]^*(v_i)) u_i \].

Therefore if we set
\[ \varphi_{i,j}(z) = u_j \cdot [\varphi(z)]^*(v_i) = ([\varphi(z)](u_j) \cdot v_i \]
the matrix of \( I - E(z) \) with respect to the basis \( u_i \) is
\[
\begin{bmatrix}
1 - \varphi_{1,1}(z) & -\varphi_{1,2}(z) & \cdots & -\varphi_{1,n}(z) & -\varphi_{1,n+1}(z) & \cdots \\
-\varphi_{2,1}(z) & 1 - \varphi_{2,2}(z) & \cdots & -\varphi_{2,n}(z) & -\varphi_{2,n+1}(z) & \cdots \\
-\varphi_{n,1}(z) & -\varphi_{n,2}(z) & \cdots & 1 - \varphi_{n,n}(z) & -\varphi_{n,n+1}(z) & \cdots \\
0 & 0 & \cdots & 0 & 1 & 0 & \cdots \\
0 & 0 & \cdots & 0 & 0 & 1 & \cdots \\
& & & & & & \\
& & & & & & 
\end{bmatrix}
\]

This matrix has the form
\[ I - E(z) = \begin{bmatrix}
I_n - \Phi(z) & N(z) \\
0 & I
\end{bmatrix},
\]
in which \( \Phi(z) \) a holomorphic function taking values in the space of \( n \times n \) complex matrices. Either \( \det (I_n - \Phi(z)) \) is identically 0, or not. In the second case, one can solve explicitly for \((I_n - E(z))^{-1}\) in terms of the cofactor matrix of \( I - \Phi(z) \). Its poles are where \( \Phi(z) \) has eigenvalue 1. Also in this case we may write for each \( n > 0 \)
\[
(I_n - E(z))^n = \begin{bmatrix}
(I_n - \Phi(z))^n & N_n(z) \\
0 & I
\end{bmatrix}
\]
which implies that the vectors annihilated by some power of \((I_n - E(z))\) are the same as those annihilated by some power of \(I_n - \Phi(z)\), which has finite dimension. This concludes the proof of the Lemma. 

The operator \(G(z)\) is of finite rank, since its image is contained in the image of \(F_0\). Thus in the neighbourhood of \(z_0\) the operator \(I - C(z)\) is invertible if and only if \(I - G(z)\) is. As for \(G(z)\), Lemma 1.5 shows that the set of points where it is invertible is either discrete, or empty. Now since \(C(0) = I, I - C(z)\) is certainly invertible in the neighbourhood of the origin, and hence by analytic continuation the operator \((I - C(z))^{-1}\) is meromorphic with a discrete set of poles. This concludes the proof of the Theorem.

1.6. **Corollary.** If \(T\) is a compact operator from a Hilbert space to itself, then its spectrum \(\sigma(T)\) is a discrete set having no limit points except possibly \(0\).

1.7. **Corollary.** If \(T\) is a self-adjoint compact operator, then for any \(\lambda \neq 0\) the eigenspace \(H_\lambda\) for \(T\) has finite dimension.

1.8. **Corollary.** A self-adjoint operator \(T\) is compact if and only if there exists orthonormal sets \(\{v_i\}\) in \(H_1\) and \(\{u_i\}\) in \(H_2\) and a set of positive \(\{\lambda_i\}\) with \(\lambda_i \to 0\) such that \(T(v_i) = \lambda_i v_i\).

**ANOTHER CHARACTERIZATION.** In this section I’ll come back to an idea brought up in the introduction to this section.

1.9. **Theorem.** The operator \(T : H_1 \to H_2\) is compact if and only if there exist orthonormal sets \(\{v_i\}\) in \(H_1\) and \(\{u_i\}\) in \(H_2\) and a set of positive \(\{\lambda_i\}\) with \(\lambda_i \to 0\) such that

\[
T(x) = \sum_{i \geq 1} \lambda_i (x \cdot v_i) u_i.
\]

These are essentially unique.

**Proof.** We have seen at the beginning of this section that \(T\) is compact if such a sequence exists.

So now assume \(T\) compact. The proof of the formula for \(T\) is motivated by the singular value decomposition in finite dimensions. If \(T = US\) with \(U\) unitary and \(S\) positive Hermitian with \(\{v_i\}\) an orthonormal basis of eigenvectors, then

\[
S(u) = \sum \lambda_i (u \cdot v_i) v_i \quad \text{and} \quad T(u) = US(u) = \sum \lambda_i (u \cdot v_i) U(v_i) = \sum \lambda_i (u \cdot v_i) u_i \quad (u_i = U(v_i)).
\]

So now we continue. Since \(T\) is compact, so is \(T^* \cdot T\). It is also positive. Therefore there exists an eigenpair sequence \(\{v_i, \mu_i\}\) (\(i \geq 1\)) with

\[
T^* \cdot T(v_i) = \mu_i v_i
\]

and \(T^* \cdot T = 0\) on the complement of the \(v_i\). Since \(\mu_i > 0\), we may define \(\lambda_i = \sqrt{\mu_i} > 0\). We have

\[
w = w_0 + \sum_{i \geq 1} (w \cdot v_i) v_i
\]

for every \(w\), where \(w_0\) lies in the kernel of \(T\), hence

\[
T(w) = \sum_{i \geq 1} (w \cdot v_i) T(v_i).
\]
Set \( u_i = T(v_i)/\sqrt{\lambda_i} \). Then
\[
 u_i \cdot u_j = \frac{T(v_i) \cdot T(v_j)}{\lambda_i \lambda_j} = \frac{T^* T(v_i) \cdot v_j}{\lambda_i \lambda_j} = \frac{\lambda_i}{\lambda_j} (v_i \cdot v_j)
\]
so \( \{v_i\} \) is an orthonormal basis for the complement of the kernel of \( T \), and
\[
 T(w) = \sum \lambda_i (w \cdot v_i) \, u_i .
\]

As for uniqueness, it is easy to see that any representation of this kind has to arise from the singular value factorization.

The \( \lambda_i \) in this result are called (what else?) the **singular values** of \( T \).

### 2. Hilbert-Schmidt operators

2.1. **Lemma.** If \( T \) is a positive operator on the Hilbert space \( H \) the sum \( \sum T(u_i) \cdot u_i \) is independent of the choice of orthonormal basis \( \{u_i\} \).

The terms are all non-negative. The sum might be infinite. Whether finite or infinite, it is called the **trace** of \( T \).

**Proof.** Let \( S = T^{1/2} \). Suppose \( \{u_i\} \) and \( \{v_i\} \) to be two orthonormal bases.
\[
 \sum_i T(u_i) \cdot u_i = \sum_i \|S(u_i)\|^2 \\
 = \sum_i \left( \sum_j |S(u_i) \cdot v_j|^2 \right) \\
 = \sum_i \|S(v_j) \cdot u_i\|^2 \\
 = \sum_i \|S(v_i)\|^2 \\
 = \sum_j T(v_j) \cdot v_j .
\]

By analogy with what happens in finite dimensions, this sum is called \( \text{trace}(T) \).

Each composite \( T^* \cdot T \) is positive. An operator \( T : H_1 \to H_2 \) is called a **Hilbert-Schmidt** operator if
\[
 \text{trace} T^* \cdot T = \sum \|T(u_i)\|^2 < \infty .
\]

for some—hence by the Lemma any—orthonormal basis \( \{u_i\} \).

Let \( \mathcal{I}_2 = \mathcal{I}_2(H_1, H_2) \) be the set of Hilbert-Schmidt operators from \( H_1 \) to \( H_2 \). Define on \( \mathcal{I}_2 \) the norm
\[
 \|T\|_2 = \text{trace} T^* \cdot T.
\]

2.2. **Proposition.** If \( T \) is any bounded operator then \( \|T\| \leq \|T\|_2 \).

**Proof.** If \( u \) is a unit vector we may choose it to be the first element of a basis, so that \( \|T u\|^2 \leq \|T\|_2^2 \). Thus \( \|T\| \leq \|T\|_2 \).

2.3. **Proposition.** The space \( \mathcal{I}_2 \) with the norm \( \|T\|_2 \) is a Hilbert space, and if \( T \) is in \( \mathcal{I}_2 \) then \( \|T\|_2 = \|T^*\|_2 \).
Proof. It is immediate that $\|\lambda T\|_2 = |\lambda| \|T\|_2$ and

$$\|S + T\|_2 \leq \|S\|_2 + \|T\|_2,$$

so the set $I_2$ is a vector space.

Suppose $\{u_i\}$ and $\{v_j\}$ to be orthonormal bases of $H_1$ and $H_2$. If $T$ is any bounded operator from $H_1$ to $H_2$

$$T(u_i) = \sum t_{i,j}v_j, \quad \|T(u_i)\|^2 = \sum_j |t_{i,j}|^2$$

so that $T$ is a Hilbert-Schmidt operator if and only if $\|T\|_2^2 = \sum |t_{i,j}|^2 < \infty$. Conversely, every such infinite matrix $(t_{i,j})$ corresponds to a unique Hilbert-Schmidt operator, and $I_2$ is in fact isomorphic to the Hilbert space of all such infinite matrices. The adjoint $T^*$ corresponds to the matrix which is the conjugate transpose of that of $T$.

2.4. **Theorem.** A Hilbert-Schmidt operator may be approximated in the $I_2$ norm by operators of finite rank.

Proof. Let $(t_{i,j})$ be the matrix corresponding to the Hilbert-Schmidt operator $T$. Thus $\sum |t_{i,j}|^2 < \infty$. Choose $n$ so $\sum_{|i,j| > n} |t_{i,j}|^2 < \varepsilon^2$. If $F$ is the operator of finite rank whose matrix is the first $n$ rows of the matrix then $\|T - F\|_2 < \varepsilon$.

2.5. **Corollary.** Hilbert-Schmidt operators are compact.

Proof. Because $\|T\| \leq \|T\|_2$.

2.6. **Proposition.** If $S$ is an arbitrary bounded operator and $T$ is Hilbert-Schmidt, then $ST$ and $TS$ are both Hilbert-Schmidt.

In other words, the linear space of Hilbert-Schmidt operators is an ideal in the ring of bounded operators.

Proof. There are two situations to investigate:

$$
\begin{align*}
H_1 & \xrightarrow{S} H_2 \xrightarrow{T} H_3 \\
H_1 & \xrightarrow{T} H_2 \xrightarrow{S} H_3.
\end{align*}
$$

On the one hand

$$\sum \|ST(u_i)\|^2 \leq \|S\|^2 \sum \|T(u_i)\|^2.$$

On the other, $TS = (S^*T^*)^*$. Apply Proposition 2.3.

2.7. **Proposition.** The operator $T$ is Hilbert-Schmidt if and only if the sum $\sum \lambda_i^2 < \infty$, where the $\lambda_i$ are the singular values of $T$.

Proof. Since

$$T(u_i) = \sum_j \lambda_j (u_i \cdot u_j) v_j = \lambda_i v_i \quad \|T(u_i)\|^2 = \lambda_i^2.$$
3. Example: differential operators on the circle

Now let $H = L^2(\mathbb{S})$, and identify $\mathbb{S}$ with $\mathbb{R}/\mathbb{Z}$. Set $Dy = y''$. The eigenvalues of $D$ are the $\mu$ with periodic solutions $y(x)$ to the equation $y'' = \mu y$. The solutions of this equation on $\mathbb{R}$ are the linear combinations of $e^{\lambda x}$ and $e^{-\lambda x}$ where $\lambda^2 = \mu$. These solutions will be periodic if and only if $\lambda = 2\pi i n$, in which case $\mu = -4\pi^2 n^2$.

3.1. Proposition. Suppose $\mu \neq -4\pi^2 n^2$ for $n \in \mathbb{Z}$. Then $D - \mu I$ is an isomorphism of the domain of $D$ with $L^2(\mathbb{S})$.

Proof. Suppose $\mu$ not to be one of these eigenvalues.

There are two ways to prove the Proposition.

The first in terms of Fourier series. If $F$ is in $L^2(\mathbb{S})$ then

$$F(x) = \sum_n F_n e^{2\pi inx}, \quad F_n = F \cdot e^{2\pi inx}.$$ 

The map taking $F$ to $(F_n)$ is an isomorphism of $L^2(\mathbb{S})$ with $L^2(\mathbb{Z})$. Since $(DF)_n = -4\pi^2 n^2 F_n$, the domain of $D$ is the subspace of those $F$ such that $n^2 F_n$ is square-integrable. The distribution $(D - \mu I) F$ has coefficients $(-4\pi^2 n^2 - \mu)F_n$, and under the assumption on $\mu$ none of the factors vanishes. The inverse of $D - \mu I$ therefore takes the function with Fourier coefficients $F_n$ to that with coefficients $F_n/(-4\pi^2 n^2 - \mu)$.

The second way to understand the inverse of $D - \mu I$ is in terms of an integral operator. If $\Phi$ is a distribution on $\mathbb{S}$, its derivative is defined by the equation

$$\langle \Phi', f \rangle = -\langle \Phi, f' \rangle,$$

leading to a formula for the second derivative

$$\langle \Phi'', f \rangle = \langle \Phi, f'' \rangle,$$

where in both cases $f$ is an arbitrary smooth function on $\mathbb{S}$. A fundamental solution of $D - \mu I$ is a distribution $F_y$ on $\mathbb{S}$ depending on the parameter $y$ such that

$$(D - \mu I) F_y = \delta_y.$$

This may be constructed explicitly, since the distribution equation amounts to the conditions that (a) $F = F_y$ is smooth and periodic on $\mathbb{R}$ of period 1 except at the points $y + n$, and (b) $F$ is continuous at these points, but $F'(y+) - F'(y-) = 1$. For any $x$ in $\mathbb{R}$ let $\lfloor x \rfloor = x - [x]$ be the fractional part of $x$. If we define

$$f(x) = \frac{e^{\lambda x} + e^{-\lambda x}}{\lambda (e^{\lambda/2} - e^{-\lambda/2})},$$

then this function satisfies these conditions at the points in $1/2 + \mathbb{Z}$. Since $D$ commutes with translations, we set

$$F_y = f(y - 1/2).$$

The formula

$$\varphi(x) = \int_0^1 \varphi(y) F_y(x) \, dy$$

defines the inverse to $D - \mu I$.

Now I want to look at a much more general situation, one in which nothing explicit can be done, but much can be said in a general way. I’ll leave out details, since the subject of Sobolev spaces deserves, and will get, a longer treatment elsewhere. Let

$$L f = -d^2 f/da^2 + a(x) f$$
where the real function $a(x)$ is smooth and periodic of order $2\pi$, and hence $L$ may be considered as an operator on $C_c^\infty(S)$, where $S$ is the unit circle. This operator is symmetric and essentially self-adjoint. We have
\[
\int_S Lf(x)\overline{f(x)}\,dx = \int_S |f'(x)|^2 + a(x)|f(x)|^2\,dx.
\]
Replacing $L$ by $L + pI$ if necessary, we may assume that $L$ is a positive operator.

3.2. Proposition. The set of eigenvalues of $L$ is infinite and discrete in $\mathbb{R}$.

For $m \geq 0$ the Sobolev space $H^m$ is that of $f$ such that every $d^k f/dx^k$ lies in $L^2(S)$ for all $k \leq m$. Fourier analysis tells us that this is the same as the distributions whose Fourier coefficients $c_\ell$ satisfy
\[
\sum (1 + |\ell|^2)^m |c_\ell|^2 < \infty.
\]
This condition defines $H^m$ for $m < 0$, too. Every $H^m$ embeds into $H^{m-1}$, and this embedding is Hilbert-Schmidt, since it is the composite of the operators
\[
(c_n) \mapsto (1 + |n|)c_n, \quad (c_n) \mapsto c_n/(1 + |n|),
\]
The second is Hilbert-Schmidt, and we know that the composite of a Hilbert-Schmidt operator and a bounded operator is Hilbert-Schmidt.

Functions in $H^m$ are in $C^{m-1}$, so the intersection of all $H^m$ is $C^\infty(S)$. Furthermore, $H^2$ is the domain of both $y \mapsto y''$ and $L$. Each of these takes $H^m$ to $H^{m-2}$.

The operator $I + L$ is in fact an isomorphism of $H^k$ with $H^{k-2}$ for all $k$. Therefore $(I + L)^{-1}$ is a compact operator, and from this we deduce an orthogonal decomposition of $L^2$ into finite-dimensional eigenspaces of $L$. If $\varphi$ is smooth and $Lf = \varphi$ then $f$ is also smooth. Hence all eigenfunctions are smooth.

4. Nuclear operators

An arbitrary bounded operator $T$ on the Hilbert space $H$ is said to be nuclear, or of trace class, if the trace of $|T|$ is finite—if
\[
\sum |T|(u_i) \cdot u_i = \sum |T|^{1/2}(u_i) \cdot |T|^{1/2}(u_i) < \infty
\]
for one, hence by Lemma 2.1 all, orthonormal bases $\{u_i\}$.

Let $I_1(H)$ be the set of nuclear operators from $H$ to itself. We shall see later how to extend the trace function to all of $I_1(H)$ (instead of just positive operators), but that will take some preparation.

4.1. Lemma. If $T$ is a positive operator and $U$ is a partial isometry then $\text{trace}(U^* T U) \leq \text{trace}(T)$. Equality holds if $U$ is unitary.

Proof. Choose a basis $\{u_i\}$ such that each $u_i$ is in either the kernel of $U$ or its perpendicular complement. The vectors $U(u_i)$ for $u_i$ in the complement may be extended to a full orthonormal basis $\{v_i\}$. Then
\[
\sum U^* T U(u_i) \cdot u_i = \sum T U(u_i) \cdot U(u_i) \leq \sum T(v_i) \cdot v_i = \text{trace}T.
\]
If $U$ is unitary, equality holds.

I do not know is the last equation remains valid when $U$ is not unitary, as it does in finite-dimensional spaces.

4.2. Proposition. The set of nuclear operators is a vector space. More precisely:
(a) if $T$ is nuclear, so is $\lambda T$;  
(b) if $S$ and $T$ are nuclear, so is $S + T$, and

$$\text{trace } |S + T| \leq \text{trace } |S| + \text{trace } |T|.$$ 

Proof. Claim (a) is immediate, but (b) is a bit tricky (even in finite dimensions).
Suppose $S$ and $T$ to be in $I_1$. Start with unitary singular-value decompositions:

$$S = U |S|$$  
$$T = V |T|$$  
$$S + T = W |S + T|,$$  

which are equivalent to

$$|S| = U^* S$$  
$$|T| = V^* T$$  
$$|S + T| = W^* (S + T).$$

Then for any $u$

$$u \bullet |S + T|u = u \bullet W^*(S + T)(u)$$  
$$\leq |u \bullet W^* U|S(u)| + |u \bullet W^* V|T|(u)|$$  
$$= |S|^{1/2} U^* W(u) \bullet |S|^{1/2}(u) + |T|^{1/2} V^* W(u) \bullet |T|^{1/2}(u)|$$  
$$\leq \| |S|^{1/2} U^* W(u) \| \cdot \| |S|^{1/2}(u) \| + \| |T|^{1/2} V^* W(u) \| \cdot \| |T|^{1/2}(u) \|$$

and thus

$$\sum_{1}^{\infty} u_i \bullet |S + T|(u_i) \leq \sum_{1}^{\infty} \| |S|^{1/2} U^* W(u_i) \| \cdot \| |S|^{1/2}(u_i) \|$$  
$$\leq \left( \sum_{1}^{\infty} \| |S|^{1/2} U^* W(u_i) \|^2 \right)^{1/2} \left( \sum_{1}^{\infty} \| |S|^{1/2}(u_i) \|^2 \right)^{1/2}$$  
$$\leq \left( \sum_{1}^{\infty} \| |T|^{1/2} V^* W(u_i) \|^2 \right)^{1/2} \left( \sum_{1}^{\infty} \| |T|^{1/2}(u_i) \|^2 \right)^{1/2}$$  
$$= \left( \sum_{1}^{\infty} \| |S|^{1/2}(u_i) \|^2 \right)^{1/2} \left( \sum_{1}^{\infty} \| |S|^{1/2}(u_i) \|^2 \right)^{1/2}$$  
$$+ \left( \sum_{1}^{\infty} \| |T|^{1/2}(u_i) \|^2 \right)^{1/2} \left( \sum_{1}^{\infty} \| |T|^{1/2}(u_i) \|^2 \right)^{1/2}$$  
$$= \text{trace } |S| + \text{trace } |T|.$$

This concludes the proof of Proposition 4.2.
4.3. **Lemma.** Every bounded linear operator from a Hilbert space to itself is a linear combination of four unitary operators.

**Proof.** If $T$ is any bounded operator, the operators $A = T + T^*$ and $B = i(T − T^*)$ are self-adjoint, and

$$T = (1/2)A − (i/2)B.$$  

So to prove the theorem, we may suppose $T$ to be self-adjoint and $\|T\| \leq 1$. Then

$$T = (1/2) \left( T + i\sqrt{I - T^2} \right) + (1/2) \left( T - i\sqrt{I - T^2} \right),$$

and each of these terms is unitary since

$$\left( T \pm i\sqrt{I - T^2} \right)^* = T \mp i\sqrt{I - T^2}, \quad \left( T \pm i\sqrt{I - T^2} \right) \left( T \mp i\sqrt{I - T^2} \right) = I.$$  

4.4. **Proposition.** If $S$ is bounded and $T$ in $I_1$ then $ST$ and $TS$ are also in $I_1$, and $\text{trace } ST = \text{trace } TS$.

**Proof.** By Lemma 4.3 we may assume $T$ unitary. Let $\{u_i\}$ be an orthonormal basis $\{v_i = T(u_i)\}$ another.

$$\text{trace } ST = \sum ST(u_i) \bullet u_i$$

$$= \sum ST(u_i) \bullet T^* T(u_i)$$

$$= \sum S(v_i) \bullet T^* (v_i)$$

$$= \sum TS(v_i) \bullet v_i$$

$$= \text{trace } TS.$$  

4.5. **Proposition.** Any operator of trace class is Hilbert-Schmidt.

**Proof.** If $T$ is of trace class then so are $|T|$ and, by Proposition 4.4, $|T|^2$. But $\text{trace } |T|^2 = \sum \|T(u_i)\|^2$.  

4.6. **Corollary.** Every operator of trace class is compact. A compact operator is in $I_1$ if and only if $\sum \lambda_i < \infty$, where the $\lambda_i$ are its singular values.

**Proof.** The first part follows from the previous two results. For the last part, if $T$ then so is $|T| = U^* T$, and its canonical expansion is

$$|T|u = \sum \lambda_i (u \bullet u_i) u_i.$$  

But then $\sum |T|u_i \bullet u_i = \sum \lambda_i$.  

Define the norm on $I_1$:

$$\|T\|_1 = \sum \lambda_i$$

where the $\lambda_i$ are the singular values of $T$.

4.7. **Proposition.** The space $I_1$ together with the norm $\|T\|_1$ is a Banach space, and $\|T\| \leq \|T\|_1$. The operators of finite rank are dense in this Banach space.

**Proof.** Exercise.  

4.8. **Proposition.** If $T$ is in $I_1$, the sum

$$\text{trace } T = \sum T(u_i) \bullet u_i$$

converges absolutely and is independent of the orthonormal basis $\{u_i\}$.  

Proof. Write the unitary singular value decomposition $T = U|T|U^* \cdot U$. Then $S = U|T|U^*$ is positive and self-adjoint, and also in $I_2$. Also, $S^{1/2}$ and $S^{1/2}U$ are in $I_2$. Hence

$$|T(u_i) \cdot u_i| = ||S^{1/2}U(u_i) \cdot S^{1/2}(u_i)|| \leq ||S^{1/2}(u_i)||$$

and

$$\sum |T(u_i) \cdot u_i| \leq \sum ||S^{1/2}U(u_i)|| ||S^{1/2}(u_i)|| \leq \left( \sum ||S^{1/2}U(u_i)||^2 \right)^{1/2} \left( \sum ||S^{1/2}(u_i)||^2 \right)^{1/2}$$

so the sum converges absolutely.

Independence is formal:

$$\sum T(u_i) \cdot u_i = \sum \left( \sum_{j} (u_i \cdot v_j) v_j \right) \cdot u_i$$

$$= \sum_{i,j} (v_j \cdot u_i) (T(v_j) \cdot u_i)$$

$$= \sum_j T(v_j) \cdot \left( \sum_i (v_j \cdot u_i) u_i \right)$$

$$= \sum_j T(v_j) \cdot v_j .$$

This concludes the proof of the Proposition.

4.9. Theorem. An operator is in $I_1$ if and only if it factors as the composite of two Hilbert-Schmidt operators.

Proof. From Proposition 4.4 and the singular value decomposition.

4.10. Corollary. For a bounded operator $S$, $\text{trace} S^* = \text{trace} S$.

Proof. This is immediate.

The following is also a corollary of the previous result.

4.11. Theorem. The operator $T$ is of trace class if and only if there exist orthonormal bases $u_i, v_i$ with

$$T(x) = \sum_i \lambda_i (x \cdot v_i) u_i ,$$

in which $\sum |\lambda_i| < \infty$. In this case its trace is

$$\sum \lambda_i (u_i \cdot v_i) .$$
5. Integral operators

The standard example of a Hilbert-Schmidt operator is an integral operator defined by a kernel function. Suppose $(M, dx)$ to be a measure space such that $L^2(M)$ is separable. (For example, $M$ could be a locally compact space with countable basis, $dx$ a Baire measure.) Let $K(x, y)$ be an $L^2$ function on $M \times M$. Then the integral formally defined as

$$[T_Kf](x) = \int_M K(x, y)f(y) \, dy$$

determines a bounded operator $T_K$ from $L^2(M)$ to itself. More precisely, it is defined by Riesz' Lemma (identifying a Hilbert space with its conjugate dual) and the equation

$$T_Kf \cdot g = \int_M K(x, y)f(y)g(x) \, dxdy$$

for every $g$ in $L^2(M)$.

**5.1. Proposition.** A bounded linear operator $T$ on $L^2(M)$ is Hilbert-Schmidt if and only if $T = T_K$ for some $K$ in $L^2(M \times M)$. Furthermore,

$$\|T_K\|_2^2 = \int_{M \times M} |K(x, y)|^2 \, dxdy.$$

**Proof.** Let $\{u_\cdot\}$ be an orthonormal basis of $L^2(M)$. Then the products $u_{i,j}(x, y) = u_i(x)u_j(y)$ are an orthonormal basis of $L^2(M \times M)$ (§II.4 of [Reed-Simon:1973]). We may therefore express

$$K = \sum_{i,j} c_{i,j} u_{i,j}.$$

We have

$$\text{trace } T_K^*T_K = \sum |c_{i,j}|^2 = \|K\|_2^2.$$

Thus $K \mapsto T_K$ is an isometric embedding of $L^2(M \times M)$ into $I_2$. It has closed range. But the finite rank operators are contained in it and are dense in $I_2$.

If $K$ is a function on the product of a finite set $S$ with itself, $T_K$ may be identified with a finite matrix, and the trace of $T_K$ is the sum $\sum K(s, s)$ of its diagonal entries. There are many generalizations of this in the literature. Most have rather restrictive hypotheses, and not all are correct. One whose hypothesis is usually easy to verify and whose proof is not too complicated can be found in [Duflo:1972].

**5.2. Theorem.** Suppose $K(x, y)$ to be a continuous square-integrable kernel function on some locally compact space $M$ with measure $dx$. If $T_K$ is of trace class, then the restriction of $K$ to the diagonal is integrable and the trace of $T_K$ is

$$\int_M K(x, x) \, dx.$$

In practice, the hypothesis is not hard to verify—for example, by seeing that $T_K$ is the product of two Hilbert-Schmidt operators. In certain circumstances the hypothesis can be simplified—if $K$ is continuous and $T_K$ is a positive operator, it will be automatically of trace class if its integral over the diagonal is finite. This is not all that useful in practice.
The proof can be easily motivated. Suppose that the functions \( u_i \) making up an orthonormal basis of \( L^2(M) \) are continuous on \( M \), and that \( K \) is defined by an absolutely and uniformly converging sum

\[
K(x, y) = \sum \lambda_i u_i(x) \overline{v}_i(y).
\]

The operator \( T_K \) takes

\[
\sum \lambda_i (w \cdot v_i) u_i
\]

and its trace is

\[
\sum \lambda_i (u_i \cdot v_i) = \sum \lambda_i \int_M u_i(x) \overline{v}_i(x) \, dx.
\]

But the assumption about convergence allows us to interchange sum and integral to get this equal to

\[
\int_M \sum \lambda_i (u_i \cdot \overline{v}_i(x)) \, dx = \int_M K(x, x) \, dx.
\]

The point of the proof is to make this argument valid. The principal problem is that convergence in (5.3) is only in the \( L^2 \)-norm, and in fact the \( u_i, v_i \) are not necessarily continuous. Continuity has to enter in somewhere, because if \( K \) is only assumed to lie in \( L^2 \) its restriction to the diagonal doesn’t make sense.

The most interesting applications of Duflo’s theorem these days are probably to automorphic forms, which is what Duflo had in mind. An early example can be found in [Duflo-Labesse:1971]. At the bottom of p. 225 the authors simply refer to a manuscript of Bourbaki—unpublished then and still unpublished now for the result above. This is presumably the same thing that Duflo refers to as the origin of his theorem.

More examples are in Arthur’s development of the Selberg trace formula. There, one wants an expression for the trace of convolution operator \( R_f \) (\( f \) in \( C^\infty_c(G) \)) on \( L^2_c(\Gamma \backslash G) \). It is relatively easy to verify that it is the composite of two Hilbert-Schmidt operators, and that its kernel is continuous. Arthur’s proof (Theorem 3.9 in [Arthur:1970]) demonstrates these points, but then to apply his version of an integral formula requires some extra work. His argument has something in common with that of Duflo, but is more elementary because his hypotheses are stronger. In subsequent accounts of the Arthur-Selberg trace formula the formula for the trace as an integral over the diagonal is always, as far as I know, passed over in an almost inaudible mumble.

There is a satisfying—perhaps close to definitive—generalization of Duflo’s (or Bourbaki’s) theorem to be found in the paper [Brislawn:1991] (a sequel to [Brislawn:1988] and [Brislawn:1990]). His main result uses a regularization process that involves martingales to make sense of the diagonal integral for any trace class kernel. It does not even assume that the space on which measures exist is locally compact, but implies Duflo’s result easily if it is. I should say that Brislawn helped me to decipher Duflo’s paper, which is somewhat elliptic and in addition contains a few confusing typographical slips.

The proof of Duflo’s theorem that I give will follow Duflo’s argument closely, and will be in several steps. In this first version of this essay I’ll quote without proof a couple of basic results in measure theory that are needed. In a later version I hope to include them in an appendix. The optimal hypotheses for these vary, but I assume here that \( M \) is a locally compact space that is equal to a countable union of compact subsets, and that it is given a regular Radon measure \( dx \). This means that open and closed subsets are measurable and that the measure of any set is the limit of measures of its closed subsets. It is not a stringent requirement.

5.4. Lemma. (Riesz) If the sequence \( f_n \) converges in \( L^p \)-norm \((p \geq 1)\) to \( f \) then there exists a subsequence which converges pointwise to \( f \) almost everywhere.

As a special case, if the sequence \( f_n \) is monotonic then the sequence itself converges almost everywhere. This result is presumably well known, but my source for it is the undated article by Péter Medvegyev in the reference list (Propositions 4 and 6).
5.5. Lemma. (Egoroff) Suppose the sequence of measurable functions $f_n$ to converge almost everywhere locally to $f$. Then for every compact subset $\Omega$ of $M$ and $\varepsilon > 0$ there exists a compact set $X \subseteq \Omega$ such that (a) $\text{meas}(\Omega - X) < \varepsilon$; (b) the restriction of each $f_n$ to $X$ is continuous; (c) the sequence $f_n$ converges uniformly on $X$ to $f$ (which is consequently continuous).

This form of Egoroff’s theorem is to be found in §IV.5.4 of [Bourbaki:2007].

5.6. Lemma. (Lusin) Suppose $X$ to be locally compact with a countable basis and Baire measure $dx$, such that $\text{meas}(X) < \infty$. If $f$ is measurable on $X$, then for each $\varepsilon > 0$ there exists a compact subset $Y$ with $\text{meas}(X - Y) < \varepsilon$ on which it is continuous.

For a simple proof, look at [Loeb-Talvila:2004].

So now I begin the proof proper of Theorem 5.2. By assumption and Theorem 4.11, There exist orthonormal bases $\{u_i\}$ and $\{v_i\}$ and a sequence $\lambda_i$ such that

$$
T_K f = \sum \lambda_i (f \ast v_i) u_i
$$

$$
\text{trace } K = \sum \lambda_i (u_i \ast v_i).
$$

Factor each $\lambda_i = \mu_i \nu_i$ with $|\mu_i| = |\lambda_i|^{1/2}, |\nu_i| = |\lambda_i|^{1/2}$. Since

$$
\sum \int_M |\lambda_i||u_i(x)|^2 \, dx = \sum |\lambda_i| < \infty
$$

$$
\sum \int_M |\lambda_i||v_i(x)|^2 \, dx = \sum |\lambda_i| < \infty,
$$

the series of functions

$$
\sum |\lambda_i||u_i(x)|^2
$$

$$
\sum |\lambda_i||v_i(x)|^2
$$

converge in $L^1$ norm.

Lemma 5.4, Lemma 5.5 and Lemma 5.6 thus imply that for every compact $\Omega \subseteq M$ and $\varepsilon > 0$ there exists a compact set $X \subseteq \Omega$ such that (a) $\text{meas}(\Omega - X) < \varepsilon$; (b) all $u_i, v_i$ are continuous on $X$; (c) both these series converge uniformly there.

Now choose an increasing sequence of compact subsets $\Omega_n$ whose union is $M$, and for each $n$ a sequence of compact subsets $X_n \subseteq \Omega_n$ verifying the properties above with $\varepsilon = 1/n$.

For each $n$ let

$$
X_n = \bigcup_{k=1}^n X_k^n, \quad X = \bigcup X_n.
$$

Each $X_n$ is compact; $X_n \subseteq X_{n+1}$; the restrictions of $u_i, v_i$ to $X_n$ are continuous; the series (c), (d) converge uniformly on $X_n$; and $M - X$ has measure 0.

Since

$$
\left( \sum |\lambda_i||u_i(x)||v_i(y)| \right)^2 \leq \left( \sum |\lambda_i||u_i(x)|^2 \right) \left( \sum |\lambda_i||v_i(y)|^2 \right),
$$

the series on the left converges uniformly on $X_n \times X_n$. For $(x, y)$ in $X \times X$, define the continuous kernel

$$
K(x, y) = \sum \lambda_i u_i(x) v_i(y).
$$
The formal argument presented earlier may now be applied to $K$. The trace of $K$ may now be evaluated as

$$\sum \lambda_i (u_i \cdot v_i) = \sum \lambda_i \int u_i(x) \overline{v_i(x)} \, dx,$$

since

$$\sum |\lambda_i| \int |v_i(x)||u_i(x)| \, dx < \infty.$$

Fubini’s Theorem allows us to interchange sum and integral to deduce that

$$\int |K(x, x)| \, dx \leq \sum |\lambda_i| \int |u_i(x)||v_i(x)| \, dx < \infty$$

and

$$\text{trace } K = \int K(x, x) \, dx.$$

On the other hand

$$\int K(x, y)f(x)g(y) \, dx \, dy = T_K f \cdot g.$$

Therefore the functions

$$K(x, y)f(x)g(y), \quad K(x, y)f(x)g(y)$$

are almost everywhere equal on $M \times M$, and in particular on $X \times X$. But they are also continuous and therefore equal on each $X_n \times X_n$, hence also on $X \times X$.
