ABSTRACT. Let $\pi_{b,c}(x)$ denote the number of primes $\leq x$ and $\equiv c(\text{mod } b)$, and for positive integers x let $\Delta_b(x,c,1) = \pi_{b,c}(x) - \pi_{b,1}(x)$. Negative values of $\Delta_4(x,3,1)$ less than 10^{12} occur in six widely spaced regions. The first three regions, investigated by Leech [6], Shanks [9], and Lehmer [6], contain only a few thousand negative values of $\Delta_4(x,3,1)$. However, the authors [1] have recently discovered 3 new regions, the sixth occurring before 20 billion and containing more than half a billion negative values of $\Delta_4(x,3,1)$. In this paper numerical and graphical details of all six regions are given. Moreover, new results for the modulus 8 are presented. Previously, no negative values have been found for $\Delta_8(x,c,1)$, c = 3,5, or 7 and our search to 10^{12} reveals no such values for $\Delta_8(x,3,1)$ or $\Delta_8(x,7,1)$. For $\Delta_8(x,5,1)$ we have discovered the first two regions of negative values. The first of these regions, beginning at x = 588067889, contains

422,500 negative values of $\Delta_8(x,5,1)$; the second occurs in the vicinity of 35 billion and contains more than a billion negative values of $\Delta_8(x,5,1)$.

1. INTRODUCTION.

Let $\pi_{b,c}(x)$ denote the number of primes $\le x$ in the arithmetic progressions $bn + c$, $1 \le c < b$, $(b,c) = 1$. For moduli b having exactly one real nonprincipal character (i.e., b = 3,4,6,8,12, and 24) and for quadratic non-residues c, let

$$\Delta_b(x,c,1) = \pi_{b,c}(x) - \pi_{b,1}(x) , \tag{1.1}$$

Due to the famous work of J. E. Littlewood [8] it is known that $\Delta_4(x,3,1)$ and $\Delta_6(x,5,1)$ assume negative values infinitely often. Knowledge regarding sign changes of $\Delta_b(x,c,1)$ has expanded considerably recently - see, for example, Knapowski and Turán [4], [5].

Somewhat surprisingly, in light of the century long interest in the phenomenon initiated by remarks of Chebyshev [3], it was not until 1957 that John Leech discovered that $\Delta_4(x,3,1)$ assumes a negative value for the first time (called a first axis crossing) at x = 26,861. Leech [6] and Shanks [9] found 3404 negative values of $\Delta_4(x,3,1)$ less than $3 \cdot 10^6$.

Based on the numerical work of Leech, of Shanks, and later work of Lehmer [7] it was believed until recently that negative values of $\Delta_b(x,c,1)$ must occur exceedingly rarely. However, the authors [1] recently discovered three new axis crossing regions for b = 4 including a thoroughly remarkable region occuring before 20 billion which contains more than half a billion integers x with $\Delta_4(x,3,1)$ negative. Our opinion that this region represents a typical state of affairs is reinforced by our discovery (see Table 1) of 1,251,299,196 negative values of

$\Delta_8(x,5,1)$ occuring between 35,615,130,497 and 37,335,021,852 whereas only 422,500 negative values occur before 35,615,130,497.

2. NOTATION AND PRELIMINARIES.

Integers x for which $\Delta_b(x,c,1)$ is negative, zero, or positive will be said to lie respectively below, on, or above the axis.

Analogous to our definition in [1] we define the ℓ-th axis crossing region for each $\ell > 1$ and fixed progression bn + c to be the ℓ-th set of consecutive positive integers $x_0(\ell)$, $x_1(\ell),\ldots,x_f(\ell)$ with the properties that (1),

$$\Delta_b(x_0(\ell),c,1) = \Delta_b(x_f(\ell),c,1) = -1 \quad , \tag{2.1}$$

and that (2) $\Delta_b(x,c,1) \geq 0$ for each integer x with $x_0(\ell) > x > x_f(\ell-1)$ and $x_0(\ell) > 2x_f(\ell-1)$. We call $x_0 = x_0(\ell)$ a first regional axis crossing and $x_f = x_f(\ell)$ a last regional axis crossing.

One of the interesting features in the interior of axis crossing regions is the existence of large negative blocks (consecutive integers with $\Delta_b(x,c,1) < 0$). In some cases a single negative block may include the majority of all integers below the axis in an axis crossing region. A non-negative block is a set of consecutive integers x with $\Delta_b(x,c,1) \geq 0$ lying inside an axis crossing region. Clearly the number of negative blocks in a region exceeds the number of non-negative blocks by exactly one.

3. AXIS CROSSING REGIONS FOR b = 4 AND b = 8 TO 10^{12}.

Tables 1 and 2 include numerical details of all regions for the moduli 4 and 8 discovered over the range to 10^{12}. The fluctuations of $\Delta_b(x,c,1)$ for $x > 10^9$ are sufficiently restrained that prime counts at intervals of 10 million, and intra-interval checking when $\Delta_b(x,c,1)$ is small, render it extremely improbable that our program overlooked any axis crossing regions beyond $x = 10^9$. For $x < 10^9$, a check was made at every prime.

The word "value" in Table 1 refers always to values of $\Delta_4(x,3,1)$ for regions 1 to 6 and to $\Delta_8(x,5,1)$ for regions 7 and 8 in table 2. All classifications are in reference to the region from the first -1 value, x_0 (the first regional axis crossing), through the last -1 value, x_f (the last regional axis crossing), except the first and last zero values which are less than x_0 and greater than x_f respectively, and the classifications "total integers on the axis" and "total integers not below the axis" which are in reference to integers between the first and last zero values. It is curious that we have found no negative values of $\Delta_8(x,3,1)$ and $\Delta_8(x,7,1)$ given the relatively small first negative values of $\Delta_4(x,3,1)$ and $\Delta_8(x,5,1)$.

Figures 1 through 8 depict regions 1 through 8 respectively (see Tables 1 and 2). Figures 9 and 10 are detailed plots of regions 4 and 7, since these regions are relatively tiny. Except for figures 9 and 10, all plots give values for 10% of the integers in the vicinity of the particular region. The lower horizontal line is the zero axis and the upper horizontal line approximates $\pi(x^{\frac{1}{2}})/4$. The equally spaced vertical lines give specific values for x and $\Delta_b(x,c,1)$. When $x > 10^8$, (figures 4 - 10) it is given in billions. With the exception of figures 1 and 2, each plot consists of about 2,000 points.
