1 Introduction

Recently, there have been lots of work on the study of higher order conformally invariant operators. A notable example is the so-called Paneitz operator (see [10])

$$Pu = \Delta^2 u + \delta \left( \frac{2}{3} K_0 I - 2\text{Ric} \right) du$$

and the associated $Q$-curvature:

$$Q = \frac{1}{12} \left( K_0^2 - \Delta K_0 - 3|\text{Ric}|^2 \right),$$

where $\delta$ denotes the divergence, $d$ the differential, $\text{Ric}$ is the Ricci curvature of $(M, g_0)$, a four dimensional manifold and $K_0$ is the scalar curvature. In [2]-[3], Chang and Yang studied the existence of extreme functions for the associated variational problem:

$$II[u] = \langle Pu, u \rangle + \int Q_0 u dV_{g_0} - \left( \int Q_0 dV_{g_0} \right) \log \int e^{4w} dV_{g_0}.$$ 

For background material and other related problems, we refer to [2], [3], [4], [6] and the references therein. The extreme function $u$ of $II[u]$ satisfies a conformal invariant elliptic equation of fourth order:

$$Pu + 2Q_0 = 2Qe^{4w}.$$ 

where $Q$ is a constant. To study the qualitative behavior (such as blow up, a priori estimates) of solutions of (3), it is important to classify all solutions to the following reduced fourth order equation

$$\Delta^2 u = 6e^{4u} \text{ in } \mathbb{R}^4, \quad \int_{\mathbb{R}^4} e^{4u} dx < \infty.$$ 

In [7] (see also [12] for higher order cases), Lin classified the solutions to (4) and proved the following theorem.

**Theorem 1.1** (Theorem 1.1 and 1.2 of [7]) Suppose $u$ is a solution to (4). Then the following statements hold true.
(i) After an orthogonal transformation, \( u(x) \) can be represented by

\[
u(x) = \frac{3}{4\pi^2} \int_{\mathbb{R}^4} e^{4u(y)} \log \frac{|y|}{|x - y|} dy - \sum_{j=1}^{4} a_j (x_j - x_j^0)^2 + c_0
\]

\[
= - \sum_{j=1}^{4} a_j (x_j - x_j^0)^2 - \alpha \log |x| + c_0 + o(1),
\]

as \( |x| \) tends to \( \infty \). Here \( a_j \geq 0 \), \( c_0 \) are constants and \( x^0 = (x_1^0, \ldots, x_4^0) \in \mathbb{R}^4 \). Moreover, if \( a_j \neq 0 \) for all \( j \), then \( u \) is symmetric with respect to the hyperplane \( \{ x \mid x_j = x_j^0 \} \). If \( a_1 = a_2 = a_3 = a_4 \), then \( u \) is radially symmetric with respect to \( x^0 \).

(ii) The total integration

\[
\alpha = \frac{3}{4\pi^2} \int_{\mathbb{R}^4} e^{4u(y)} dy \leq 2.
\]

If \( \alpha = 2 \), then all \( a_j \) are zero and \( u \) has the following form:

\[
u(x) = \log \frac{2\lambda}{1 + \lambda^2 |x - x^0|^2}, \quad \text{with} \quad \lambda > 0.
\]

(iii) If \( u(x) = o(|x|^2) \) at \( \infty \), then \( \alpha = 2 \).

Lin’s theorem shows a striking difference between (4) and its second order analogue:

\[
\Delta u + e^{2u} = 0 \quad \text{in} \quad \mathbb{R}^2, \quad \int_{\mathbb{R}^2} e^{2u} dx < \infty.
\]

It is known (see [5]) that all solutions to (7) are radially symmetric (with respect to one point) and have the form (6).

An interesting question in Lin’s theorem is: given any \( a_j \geq 0 \), \( 1 \leq j \leq 4 \) and \( \alpha > 0 \), are there solutions to (4) satisfying (5)? In the case \( a_1 = a_2 = a_3 = a_4 \), by Lin’s theorem, solutions are radially symmetric up to translation. Chang and Chen [1] proved the existence of radially symmetric solutions to (4) for any \( \alpha \in (0, 2) \). It remains to study the nonradially symmetric case, that is exactly the purpose of this paper.

Here, we show that the converse of Lin’s theorem is also true.

**Theorem 1.2** Let \( x^0 \in \mathbb{R}^4 \), \( 1 \leq k \leq 4 \), \( \alpha \in (1 - \frac{k}{4}, 2) \) and \( a_j > 0 \) for \( 1 \leq j \leq k \). Then there exists \( c_0 \in \mathbb{R} \) and a solution of (4) such that

\[
v(x) = - \sum_{j=1}^{k} a_j (x_j - x_j^0)^2 - \alpha \log |x| + c_0 + o(1)
\]

for \( |x| \) tends to \( \infty \). Moreover,

\[
\int_{\mathbb{R}^4} e^{4u(x)} dx = \frac{4\pi^2 \alpha}{3}.
\]

**Remark 1.3** Lin remarked that the condition \( \alpha > 1 - \frac{k}{4} \) is necessary for the existence of solution if we have just \( a_j > 0 \) for \( 1 \leq j \leq k \); see the comments under (3.8) in page 224 of [7]. Our result means that this condition is also sufficient. Note that when \( k = 4 \), this condition becomes just \( \alpha \in (0, 2) \), so we recover the result in [1].

Theorem 1.2 shows that there are abundant nonradially symmetric solutions to the conformally invariant equation (4). More precisely, for any \( \alpha \in (0, 2) \), even up to translation and the gauge transformation \( u(\lambda x) + 4 \log \lambda \), there exist infinitely many nonradial solutions. This is quite surprising.

In the next section, we shall prove Theorem 1.2. We make use of an idea of McOwen [8], where he constructed solutions to

\[
\Delta u + k(x) e^{2u} = 0 \quad \text{in} \quad \mathbb{R}^2,
\]

with prescribed asymptotic behavior. Our difficulty is to show a priori estimates, our main arguments are blow-up analysis and Pohozaev’s identity.
2 Proof of Theorem 1.2

Fix $1 \leq k \leq 4$, $a_j > 0$ for $1 \leq j \leq k$ and $1 - k/4 < \alpha < 2$. Using translation, we can assume that $x^0 = 0$. First, we fix a radially symmetric function $u_0 \in C^\infty(\mathbb{R}^4)$ such that $u_0(x) = -\log |x|$ for any $|x| \geq 1$. Clearly, $\Delta^2 u_0$ is compactly supported and

$$
\int_{\mathbb{R}^4} \Delta^2 u_0(x) dx = 8\pi^2.
$$

Define

$$
v = u + \sum_{j=1}^k a_j x_j^2 - \alpha u_0 \overset{\text{def}}{=} u + u_1 - \alpha u_0.
$$

Then $u$ is a solution of (4) if and only if $\Delta^2 v = K e^{4v} - \alpha \Delta^2 u_0$ where $K(x) = 6 e^{-4} u_1 + 4 \alpha u_0$.

For constructing $v$, we shall use some ideas of McOwen. Let $\mathcal{M}_{s,\delta}^p$ be the weighted Sobolev spaces, the completion of $C_0^\infty(\mathbb{R}^4)$ with the norm

$$
\sum_{|\ell| \leq s} \left\| (1 + |x|^2)^{(\delta + |\ell|)/2} D^\ell \phi \right\|_{L^p(\mathbb{R}^4)}
$$

where $p \in (1, \infty), s \in \mathbb{N}$ and $\delta \in \mathbb{R}$. Let $L^p_\delta = \mathcal{M}_{0,\delta}^p$. The following are some useful properties of $\mathcal{M}_{s,\delta}^p$ (cf. [9]).

**Lemma 2.1** Let $p > 1$ and $\delta \in (-\frac{4}{p}, \frac{4}{p} + 1)$. Then the operator $\Delta^2$ is an isomorphism from $\mathcal{M}_{4,\delta}^p$ into

$$
\Lambda = \left\{ f \in L^p_{4+\delta}, \quad \int_{\mathbb{R}^4} f dx = 0 \right\}.
$$

On the other hand, if $p > 1$, $\delta > -4/p$ and $s > 4/p$, $\mathcal{M}_{s,\delta}^p$ is compactly embedded in $C_0(\mathbb{R}^4)$.

Here $C_0(\mathbb{R}^4)$ denotes the space of continuous functions which tend to zero at $\infty$, endowed with the norm $\| \cdot \|_{C_0}$.

**Remark 2.2** For $1 \leq k \leq 4$, if $a_j > 0$ for $1 \leq j \leq k$ and $\alpha > 1 - k/4$, we can always choose $p > 1$ and $\delta \in (-\frac{4}{p}, \frac{4}{p} + 1)$ such that $K \in L^p_{4+\delta} \cap L^1(\mathbb{R}^4)$. In fact, a sufficient condition is just $p(4\alpha - \delta - 4) > 4 - k$.

For any $v \in C_0(\mathbb{R}^4)$, define

$$
c_v = \frac{\log (8\pi^2 \alpha)}{4} - \frac{1}{4} \log \left( \int_{\mathbb{R}^4} K e^{4v} dx \right).
$$

Thanks to remark 2.2, $c_v$ is well defined and it is easy to see that $K e^{4(v+c_v)} - \alpha \Delta^2 u_0$ belongs to $\Lambda$ for suitable $p > 1$ and $\delta \in (-\frac{4}{p}, \frac{4}{p} + 1)$. By lemma 2.1, there exists unique $\varphi \in \mathcal{M}_{4,\delta}^p$ such that $\Delta^2 \varphi = K e^{4(v+c_v)} - \alpha \Delta^2 u_0$; we define then $\varphi = T v$. Applying again lemma 2.1, $T$ is a continuous and compact mapping from $C_0(\mathbb{R}^4)$ into itself. Now we will try to find a fixed point for $T$, which enables us to get a solution of (4).

In our analysis, a crucial argument is the following result.

**Lemma 2.3** Let $u$ be a smooth function satisfying $\Delta^2 u = K e^{4u}$ in $\overline{B_1} \subset \mathbb{R}^4$, such that $K$ is continuous et positive in $\overline{B_1}$,

$$
\int_{B_1} K e^{4u} dy \leq \beta < 16\pi^2.
$$

and there exists $C_0 > 0$ verifying

$$
\forall B(x, r) \subset \overline{B_1}, \quad \|\Delta u\|_{L^1(B(x, r))} \leq C_0 r^2.
$$

Then there exists $C \in \mathbb{R}$ (depending on $\beta$ and $C_0$) such that

$$
\max_{B_{1/4}} u \leq C.
$$
The proof of this lemma is given by contradiction and blow-up analysis. One of the key points is that the condition (*) remains stable under the gauge transformation \( u_\lambda(y) = u(x + \lambda y) + 4 \log \lambda \). Moreover, this condition prevents to have some \( a_j > 0 \) for the solution after the blow-up, which will force the total integration to be just \( 16\pi^2 \) and contradicts then \( \beta < 16\pi^2 \).

**Proof of lemma 2.3.** Suppose that the constant \( C \) does not exist, so we have a family of smooth functions \( u_n \) such that \( \Delta^2 u_n = K e^{4u_n} \) in \( B_1 \), verifies (*) and

\[
\int_{B_1} K e^{4u_n} \, dy \leq \beta, \quad \lim_{n \to \infty} \max_{B_{1/4}} u_n \geq n.
\]

Consider

\[
h_n(x) = u_n(x) + 4 \log \left( \frac{1}{2} - |x| \right) \quad \text{in} \quad B_{1/2}.
\]

Then \( \max_{B_{1/2}} h_n \geq n - 4 \log 4 \to \infty \). Define

\[
\mu_n = h_n(x_n) = \max_{B_{1/2}} h_n, \quad \sigma_n = \frac{1}{2} - |x_n| \quad \text{and} \quad \lambda_n = \sigma_n e^{-\mu_n/4}.
\]

Clearly \( \sigma_n/\lambda_n \to \infty \). Define also \( w_n(y) = u_n(x_n + \lambda_n y) + 4 \log \lambda_n \). For \( |y| \leq \sigma_n/(2\lambda_n) \), we have

\[
\frac{1}{2} - |x_n + \lambda_n y| \geq \frac{1}{2} - |x_n| - \lambda_n |y| \geq \sigma_n - \frac{\sigma_n}{2} = \frac{\sigma_n}{2},
\]

hence

\[
w_n(x_n + \lambda_n y) \leq \mu_n - 4 \log \left( \frac{\sigma_n}{2} \right) = -4 \log \lambda_n + \log 16.
\]

In other words, \( w_n(y) \leq \log 16 \) for \( |y| \leq \sigma_n/(2\lambda_n) \). Therefore, we obtain

\[
\left\{ \begin{array}{ll}
\Delta^2 w_n = K(x_n + \lambda_n y)e^{4w_n} & \text{in} \quad B_{\sigma_n/(2\lambda_n)} \\
|w_n| \leq \log 16 & \text{in} \quad B_{\sigma_n/(2\lambda_n)} \\
w_n(0) = 1.
\end{array} \right.
\]

Moreover, for any \( R > 0 \), \( y_0 \in \mathbb{R}^4 \) such that \( B(y_0, R) \subset B_{\sigma_n/(2\lambda_n)} \), the condition (*) implies

\[
\int_{B(y_0, R)} |\Delta w_n| \, dy = \frac{1}{\lambda_n^2} \int_{B(x_n + \lambda_n y_0, \lambda_n R)} |\Delta u_n| \, dx \leq C_0 R^2.
\]

Using standard elliptic theory, it is not difficult to prove

**Lemma 2.4** Let \( R > 0 \) and \( w \) be a family of functions satisfying \( w(0) = 1 \) and

\[
\|\Delta^2 w\|_{L^\infty(B_R)} + \|\Delta w\|_{L^1(B_R)} + \sup_{B_R} w \leq A,
\]

then there exists \( C_R > 0 \) depending on \( R \) and \( A \) such that \( w \leq -C_R \) in \( B_{R/2} \).

Applying this result on \( w_n \). Up to a subsequence, we can assume that \( x_n \to x_* \), \( w_n \to w \) in \( C_0^{\infty}(\mathbb{R}^4) \), solution of

\[
\Delta^2 w = K(x_*) e^{4w} \quad \text{in} \quad \mathbb{R}^4
\]

and

\[
\int_{\mathbb{R}^4} K(x_*) e^{4w} \, dy \leq \liminf_{n \to \infty} \int_{B_{\sigma_n/(2\lambda_n)}} K(x_n + \lambda_n y)e^{4w_n} \, dy \leq \beta < 16\pi^2.
\]

Noting that \( K(x_*) \) is a constant, \( w \) must be a solution given by (5), then

\[
\Delta w(x) = -\frac{K(x_*)}{4\pi^2} \int_{\mathbb{R}^4} \frac{e^{4w(y)}}{|x - y|^2} \, dy - 2 \sum_{j=1}^4 a_j = O(|x|^{-2}) - 2 \sum_{j=1}^4 a_j.
\]

Otherwise, if we take limit in (15), we get \( \|\Delta w\|_{L^1(B_R)} \leq C_0 R^2 \) for any \( R > 0 \). Since \( a_j \geq 0 \), all the coefficients \( a_j \) must be equal to zero. By Lin’s result, we have \( w(y) = o(|y|^2) \), hence

\[
\int_{\mathbb{R}^4} K(x_*) e^{4w} \, dy = 16\pi^2,
\]

which is a contradiction. Our proof is completed. \( \square \)
Remark 2.5 We can prove similar results for a family of equicontinuous functions $K_n$ which verifies $0 < a < K_n < b < \infty$. The gauge transformation yields also that the result is true in all ball $B_R$.

Proof of Theorem 1.2 completed. Suppose that $v$ is a fixed point for the operator $\tau \mathbb{T}$ in $C_0(\mathbb{R}^4)$ with $t \in (0,1]$, that is $v = \tau \mathbb{T} v$ and $v \in C_0(\mathbb{R}^4)$. We claim then

$$v(x) = -\frac{t}{8\pi^2} \int_{\mathbb{R}^4} \log |x-y| K e^{4(v+c_0) + t \alpha u_0} + C_1 \equiv \bar{v}(x) + C_1. \quad (16)$$

Indeed, as $e^{4(v+c_0)} \in L^\infty(\mathbb{R}^4)$, under the assumption on $\alpha$ and $k$, $\bar{v}$ is well defined. It is clear that $\Delta^2(\bar{v} - v) = 0$ in $\mathbb{R}^4$. Moreover, since for $|x| > 1$,

$$\bar{v}(x) = \frac{t}{8\pi^2} \int_{\mathbb{R}^4} K e^{4(v+c_0)} \log \frac{|x|}{|x-y|} dy \quad (17)$$

and $K e^{4(v+c_0)} \in C_0 \cap L^1(\mathbb{R}^4)$, we get $\bar{v}(x) = o(\log |x|)$ at $\infty$. Liouville’s theorem yields then $v - \bar{v} \equiv$ constant.

Take

$$w = v + c_v + t \alpha u_0 + \frac{\log t}{4},$$

then $\Delta^2 w = Q e^{4w}$ in $\mathbb{R}^4$ with

$$Q = K e^{-4t \alpha u_0} = 6e^{-4\sum \alpha_j x_j^2 + (1-t) \alpha u_0}.$$ 

Clearly,

$$\int_{\mathbb{R}^4} Q e^{4w} dx = t \int_{\mathbb{R}^4} K e^{4(v+c_0)} dx \leq 8\pi^2 \alpha < 16\pi^2,$$

since $t \in (0,1]$ and $\alpha < 2$. On the other hand, thanks to (16),

$$\Delta w(x) = -\frac{1}{4\pi^2} \int_{\mathbb{R}^4} Q e^{4w} |x-y|^2 dy.$$ 

Since $-\Delta w \geq 0$ and

$$-\int_{B(x_0,r)} \Delta w(x) = \frac{1}{4\pi^2} \int_{\mathbb{R}^4} Q e^{4w(y)} \int_{B(x_0, r)} \frac{1}{|x-y|^2} dxdy \leq \frac{1}{4\pi^2} \int_{\mathbb{R}^4} Q e^{4w(y)} \int_{B(y, r)} \frac{1}{|x-y|^2} dxdy \leq \frac{t^2}{4} \int_{\mathbb{R}^4} Q e^{4w(y)} dy \leq 2\pi^2 \alpha r^2.$$ 

Thus $w$ satisfies the condition $(*)$. By lemma 2.3 and remark 2.5, we obtain then $w$ is locally uniformly upper bounded. Using the representation formula, we get also $|\nabla w|$ and $\Delta v$ are locally bounded, as $e^{4w}$ is locally bounded. For example, fix $R > 0$, for any $x \in B_R$,

$$|\Delta v(x)| = |\Delta w(x)| = \frac{1}{4\pi^2} \int_{\mathbb{R}^4} Q e^{4w} |x-y|^2 dy \leq \frac{1}{4\pi^2} \int_{B_{2R}} Q e^{4w} |x-y|^2 dy + \frac{1}{4\pi^2} \int_{\mathbb{R}^4 \setminus B_{2R}} Q e^{4w} |x-y|^2 dy \leq C_R \int_{B_{2R}} \frac{1}{|x-y|^2} dy + \frac{1}{4\pi^2 R^2} \int_{\mathbb{R}^4 \setminus B_{2R}} Q e^{4w} dy \leq C_R + \frac{2\alpha}{R^2}.$$ 

From the uniform upper bound of $w$, it follows then $\bar{w} = v + c_v + \log t/4$ is locally uniformly upper bounded. So we conclude
Lemma 2.6 Let \( k, a_j \) and \( \alpha \) be as in Theorem 1.2. For any \( R > 0 \), there exists \( C_R > 0 \) such that if \( v = tTv \) with \( t \in (0, 1) \),

\[
\sup_{B_R} v + c_t + \log t + \|\nabla v\|_{L^\infty(B_R)} + \|\Delta v\|_{L^\infty(B_R)} \leq C_R.
\]

It remains to study the exterior domain. For that, we apply the Pohozaev’s identity (see [11]). For any \( R \geq 1 \), as \( \text{supp}(\Delta^2 u_0) \subset \overline{B}_1 \),

\[
\int_{B_1} Ke^{4\pi\sigma}dx + \frac{1}{4} \int_{B_1} (x \cdot \nabla K)e^{4\pi\sigma}dx
\]

(18)

\[
= -\int_{B_1} \alpha(x \cdot \nabla v)\Delta^2 u_0 dx + \frac{1}{4} \int_{\partial B_1} K(x)|x|e^{4\pi\sigma}dx
\]

\[
- \int_{\partial B_R} |x|\left(\frac{\Delta v}{2} \right)^2 d\sigma + \int_{\partial B_R} \frac{\partial u}{\partial r} \frac{\partial (\Delta v)}{\partial r} d\sigma + \int_{\partial B_R} \Delta v \frac{\partial}{\partial r} \left( \frac{\partial v}{\partial r} \right) d\sigma.
\]

By lemma 2.6, we know that the first term in the right-hand side is uniformly bounded. The following lemma shows the behavior of last three terms, its proof is technical and delayed to the next section. There we will use intensively the assumption \( \alpha > 1 - k/4 \).

Lemma 2.7 Let \( k, a_j \) and \( \alpha \) be as in Theorem 1.2. For each fixed \( v \) satisfying \( v = tTv \) with \( t \in (0, 1) \), the last three terms in (18) tend to zero as \( R \to \infty \).

Since

\[
\forall x \in \mathbb{R}^k \setminus B_1, \quad x \cdot \nabla K = -\left( \sum_{j \leq k} 8a_j x_j^2 + 4\alpha|x| \right) K \leq 0,
\]

passing to the limit \( R \to \infty \) in (18), we obtain

\[
-\frac{1}{4} \int_{\mathbb{R}^k} (x \cdot \nabla K)e^{4\pi\sigma}dx \leq \int_{B_1} \alpha(x \cdot \nabla v)\Delta^2 u_0 dx + \int_{\mathbb{R}^k} Ke^{4\pi\sigma}dx.
\]

Using again lemma 2.6,

\[
\alpha R \int_{\mathbb{R}^k \setminus B_R} Ke^{4\pi\sigma}dx \leq C + 8\pi^2 t\alpha + \frac{1}{4} \int_{B_1} (x \cdot \nabla K)e^{4\pi\sigma}dx \leq C', \quad \text{if} \quad R > 1.
\]

For any \( \varepsilon > 0 \), there exists \( R_0 > 1 \) (depending only on \( \varepsilon \)) such that

(19)

\[
\int_{\mathbb{R}^k \setminus B_{R_0}} Ke^{4\pi\sigma}dx \leq \varepsilon.
\]

As \( \alpha > 1 - k/4 \), we can verify that \( |x|^{-8}K|x|^{-2} \in L^p(B_1) \) for some \( p > 1 \). Choose \( \varepsilon = 16\pi^2/q \) where

\[
q = \frac{p(p+1)}{p-1},
\]

and \( R_0 \) such that (19) holds. Consider the Kelvin’s transformation

\[
\zeta = \overline{w} \circ \varphi \quad \text{with} \quad \varphi(x) = \frac{R_0 x}{|x|^2} \quad \text{for} \quad |x| \leq 1.
\]

Therefore \( \Delta^2 \zeta = R_0^4 |x|^{-8} K \circ \varphi(x) e^{4\zeta} \) in \( B_1 \), since \( \text{supp}(\Delta^2 u_0) \subset \overline{B}_1 \). As

\[
\int_{B_1} R_0^4 |x|^{-8} K \circ \varphi(x) e^{4\zeta}dx = \int_{\mathbb{R}^k \setminus B_{R_0}} Ke^{4\pi\sigma}dx \leq \varepsilon,
\]

by Mösner-Trudinger’s inequality (see [7]), the upper bound for \( \zeta \) and \( |\Delta \zeta| \) on \( \partial B_1 \), we can prove \( |e^{4\zeta}|_{L^1(B_1)} \leq C \) so that \( ||x|^{-8}K \circ \varphi(x)e^{4\zeta}||_{L^{(p+1)/2}(B_1)} \leq C \). Thus \( \zeta \) is uniformly upper bounded in \( B_1 \) by elliptic theory.
Finally, \( \overline{w} \) is uniformly upper bounded in \( \mathbb{R}^4 \setminus B_{R_0} \), so \( \overline{w} \) is uniformly upper bounded in \( \mathbb{R}^4 \). Furthermore, as \( \Delta^2 v = Ke^{4\overline{w}} - t\alpha \Delta^2 u_0 \), we get easily that \( v \) is uniformly bounded by lemma 2.1, that is

\[
\text{If } v \in C_0(\overline{\mathbb{R}^4}), \quad v = t\text{Te} \text{ with } t \in (0,1], \quad \text{then } \|v\|_\infty \leq C.
\]

In conclusion, as \( T \) is compact, the Leray-Schauder's theory ensures the existence of a fixed point \( v \) for \( T \), so we get the desired solution as \( u = v - u_1 + \alpha u_0 \).

\[
\square
\]

3 Proof of Lemma 2.7

For fixed \( v \), we recall the Pohozaev identity (18)

\[
\int_{B_n} Ke^{4\overline{w}} dx + \frac{1}{4} \int_{B_n} (x \cdot \nabla K)e^{4\overline{w}} dx
\]

\[
= -\int_{B_1} t\alpha (x \cdot \nabla v) \Delta^2 u_0 dx + \frac{1}{4} \int_{\partial B_n} K(x)|x|e^{4\overline{w}} dx
\]

\[
- \int_{\partial B_n} \frac{|x|}{2} \Delta v dx - \int_{\partial B_n} |x| \frac{\partial v}{\partial \nu} (\Delta v) dx + \int_{\partial B_n} \Delta v \frac{\partial v}{\partial \nu} (r \frac{\partial v}{\partial \nu}) dx
\]

\[
= J_1 + J_2 + J_3 + J_4 + J_5.
\]

We claim then, under the condition of Theorem 1.2 for \( \alpha \) and \( a_j \),

\[
\lim_{R \to \infty} J_3 = \lim_{R \to \infty} J_4 = \lim_{R \to \infty} J_5 = 0.
\]

Remark 3.1 By similar arguments, we can also show that \( \lim_{R \to \infty} J_2 = 0 \), but it is not necessary for the proof of Theorem 1.2.

In fact, for \( |x| > 1 \),

\[
|x|^2 \Delta v(x) = -\frac{|x|^2}{4\pi^2} \int_{\mathbb{R}^4} \frac{Ke^{4\overline{w}}}{|x - y|^2} dy - |x|^2 t\alpha \Delta u_0 = \frac{|x|^2}{4\pi^2} \int_{\mathbb{R}^4} \frac{Ke^{4\overline{w}}}{|x - y|^2} dy + 2t\alpha
\]

\[
= \frac{1}{4\pi^2} \int_{\mathbb{R}^4} Ke^{4\overline{w}} \left[ 1 - \frac{|x|^2}{|x - y|^2} \right] dy
\]

\[
= \frac{1}{4\pi^2} \int_{\mathbb{R}^4} \frac{|y|^2 - 2x \cdot y}{|x - y|^2} Ke^{4\overline{w}} dy
\]

We decompose the integral over three sub-domains, \( \Omega_1 = \{|y| \leq R_1\} \); \( \Omega_2 = B(x, |x|/2) \) and \( \Omega_3 = \mathbb{R}^4 \setminus (\Omega_1 \cup \Omega_2) \), assuming that \( |x| = R > 2R_1 > 2 \).

On \( \Omega_3 \), since \( |x - y| \geq |x|/2 \) implies \( |x - y| \geq |y|/4 \) (we can discuss the cases \( |y| \leq 2|x| \) and \( |y| \geq 2|x| \)), by taking \( R_1 \) big enough (depending on \( v \)),

\[
\left( \int_{\Omega_3} \frac{|y|^2 - 2x \cdot y}{|x - y|^2} Ke^{4\overline{w}} dy \right) \leq C \int_{\mathbb{R}^4 \setminus B_{R_1}} Ke^{4\overline{w}} dy \leq \varepsilon.
\]

Fix \( R_1 \), for \( |x| > 2R_1 \),

\[
\left( \int_{\Omega_1} \frac{|y|^2 - 2x \cdot y}{|x - y|^2} Ke^{4\overline{w}} dy \right) \leq C|x|^{-1}.
\]

It remains to consider \( \Omega_2 \) where \( |y| \leq 3|x|/2 \). Denote \( \overline{y} = (y_j)_{1 \leq j \leq k} \in \mathbb{R}^k \) for any \( y \in \mathbb{R}^4 \),

\[
\int_{\Omega_2} \frac{|y|^2 - 2x \cdot y}{|x - y|^2} Ke^{4\overline{w}} dy \leq C \int_{\Omega_2} \frac{|y|^2 e^{-|\overline{y}|^2}}{|x - y|^2} |y|^{-4\alpha} dy
\]

\[
= CR^{4-4\alpha} \int_{B(\xi, 1/2)} \frac{e^{-|\overline{y}|^2}}{|\xi - \eta|^2} ||y|^{-4\alpha} dy
\]
where \( a = \min_{1 \leq j \leq 3} a_j \) is positive and we use the change of variables \( x = R\xi \) and \( y = R\eta \). Since \( |\eta| \geq 1/2 \), we have

\[
|x|^2 \Delta v(x) = O(\varepsilon) + O(R^{-1}) + O(A_2)
\]

where

\[
A_2 = \frac{\alpha}{R^{4-4\alpha}} \int_{B(1/2)} e^{-aR^2|\eta|^2} |\xi - |\eta||^2 d\eta.
\]

with \( |\xi| = 1 \). Similarly, if \( |x| = R > 2R_1 \), by decomposing \( \mathbb{R}^4 \) as above,

\[
|x| \frac{\partial v}{\partial r}(x) = -\frac{1}{8\pi^2} \int_{\mathbb{R}^4} \frac{x \cdot (x - y)}{|x - y|^4} K e^{4\pi|y|} dy + t\alpha = \frac{1}{8\pi^2} \int_{\mathbb{R}^4} \frac{y \cdot (x - y)}{|x - y|^2} K e^{4\pi|y|} dy
\]

\[
= O(\varepsilon) + O(R^{-1}) + O(A_1),
\]

and

\[
|x| \frac{\partial}{\partial r} \left( r \frac{\partial v}{\partial r} \right)(x) = \frac{1}{4\pi^2} \int_{\mathbb{R}^4} \frac{|x|^2 \cdot y - (x \cdot y)x}{|x - y|^4} K e^{4\pi|y|} dy
\]

\[
+ \frac{1}{8\pi^2} \int_{\mathbb{R}^4} \frac{x \cdot y}{|x - y|^2} K e^{4\pi|y|} dy
\]

\[
= O(\varepsilon) + O(R^{-1}) + O(A_2) + O(A_3),
\]

and

\[
|x|^3 \frac{\partial (\Delta v)}{\partial r}(x) = \frac{1}{2\pi^2} \int_{\mathbb{R}^4} \frac{|y|^2 - 2x \cdot y}{|x - y|^4} K e^{4\pi|y|} dy + 4t\alpha
\]

\[
= \frac{1}{2\pi^2} \int_{\mathbb{R}^4} \frac{|y|^2 - 2x \cdot y}{|x - y|^2} - \frac{|x|^2 (x \cdot y) \cdot y}{|x - y|^4} K e^{4\pi|y|} dy.
\]

\[
= O(\varepsilon) + O(R^{-1}) + O(A_2) + O(A_3)
\]

Here

\[
A_j(x) = \frac{\alpha}{R^{4-4\alpha}} \int_{B(1/2)} e^{-aR^2|\eta|^2} |\xi - |\eta||^j d\eta, \quad \forall 1 \leq j \leq 3
\]

with \( |\xi| = 1 \). Of course, \( A_1 \leq 2A_2 \) and \( A_2 \leq 2A_3 \), so it suffices to estimate \( A_3 \).

If \( k = 4 \), it is easy to see that \( e^{-aR^2|\eta|^2} \leq e^{-aR^2/4} \) in \( B(1/2) \) since \( |\eta| > 1/2 \), so \( \|A_3\|_{L^n(B_R)} = o(1) \) as \( R \) tends to infinity. Finally, (20) follows easily from

\[
\lim_{|x| \to \infty} \frac{|x|^2}{|x|} \frac{\partial v}{\partial r} = \lim_{|x| \to \infty} \frac{|x|^3}{|x|} \frac{\partial (\Delta v)}{\partial r} = \lim_{|x| \to \infty} |x| \frac{\partial}{\partial r} \left( r \frac{\partial v}{\partial r} \right) = 0.
\]

### 3.1 Case \( k = 1 \)

Consider now \( k = 1 \). By rearrangement argument, the integral of \( fg \) is less than that of their Schwarz-symmetrizations \( f^*g^* \). Applying that to each hyperplane \( \eta_2 \leq \xi \leq \xi_2 = \text{constant} \), we obtain

\[
\int_{B(1/2)} e^{-aR^2|\eta|^2} |\xi - \eta|^2 d\eta = \int_{B(0,1/2)} e^{-aR^2|\xi|^2} d\eta \leq \int_{B(0,1/2)} e^{-aR^2|\eta|^2} d\eta.
\]

Using the sphere coordinates, \( \eta_1 = r \cos \theta, \eta_2 = r \sin \theta \cos \varphi \) etc, we get

\[
R^{4-4\alpha} A_3 \leq C \int_0^{1/2} \int_0^{\pi/2} e^{-aR^2 r^2 \cos^2 \theta \sin^2 \varphi} \theta dr d\theta = C \int_0^{1/2} \int_0^1 e^{-aR^2 r^2 \sqrt{1 - t^2}} dt ds dt = C (I_1 + I_2)
\]
where

\[
I_1 = \int_0^{1/2} \int_0^{1/2} e^{-AR^2 \rho_1^2} \sqrt{1-t^2} ds dt \leq \frac{1}{2} \int_0^{1/2} \int_0^{1/2} e^{-aR^2 s^2 / 4} ds \leq \frac{1}{R} \int_0^\infty e^{-as^2} ds = \frac{C}{R}
\]

and

\[
I_2 = \int_0^{1/2} \int_0^{1/2} e^{-AR^2 \rho_2^2} \sqrt{1-t^2} ds dt \leq \frac{1}{R} \int_0^{\sqrt{\pi}/2} \int_0^{\sqrt{\pi}/2} e^{-as^2} ds dt \leq \frac{C \log R}{R},
\]

thanks to the following lemma.

**Lemma 3.2** Let

\[
\ell(M) = \int_0^M \int_0^M e^{-as^2} ds dt,
\]

then \(\ell(M) = O(\log M)\) as \(M\) tends to \(\infty\).

Therefore \(A_3 = O(R^{3-\alpha} \log R)\), then \(\lim_{R \to \infty} \|A_3\|_{L^\infty(B_R)} = 0\) as \(\alpha > 3/4\). Since \(\varepsilon\) is arbitrary, we obtain easily (27). We finish by the proof of lemma 3.2. Indeed (for \(M \geq 1\)),

\[
\ell(M) = 2 \int_0^M \int_0^M e^{-as^2} ds dt = 2 \int_0^M \int_0^1 e^{-as^2} ds dt = \int_0^M \int_0^1 e^{-as^2} ds dt
\]

\[
\leq C + \int_1^M \left( \int_0^\infty e^{-as^2} ds \right) dt
\]

\[
= C + C' \int_1^M \frac{ds}{s}
\]

which yields \(\ell(M) \leq C \log M\) for all \(M \geq 2\).

### 3.2 Case \(k = 2\)

In this case, we take the change of variables \(\eta_1 + i\eta_2 = r \cos \theta e^{i\psi}\) and \(\eta_3 + i\eta_4 = r \sin \theta e^{i\psi}\).

\[
R^{4-\alpha} A_2 \leq \int_{B(0,1/2)} e^{-AR^2(\eta_1^2 + \eta_2^2)} |\eta|^2 \eta d\eta \leq C \int_0^{1/2} \int_0^{\pi/2} e^{-aR^2 \cos^2 \theta} r \sin \theta \cos \theta r dr d\theta
\]

\[
= \frac{C}{R^2} \int_0^{1/2} \frac{1}{r} \left( 1 - e^{-aR^2 r^2} \right) dr
\]

\[
= \frac{C}{R^2} \int_0^{R/2} \frac{1}{s} \left( 1 - e^{-as^2} \right) ds
\]

\[
\leq \frac{C \log R}{R^2}.
\]

Therefore, \(A_2 = O(R^{2-\alpha} \log R)\) and tends uniformly to zero as \(\alpha > 1/2\). Consequently,

\[
\lim_{|x| \to \infty} |x|^2 \Delta u = \lim_{|x| \to \infty} |x| \frac{\partial u}{\partial r} = 0.
\]

For \(A_3(x)\), we cannot prove a uniform estimate tending to zero at \(\infty\) as in previous case. However, we show that \(\lim_{R \to \infty} \|A_3\|_{L^1(0,B_R)} = o(R^3)\) by suitable pointwise estimate. In fact, denote \(y = (y_1, y_2)\) and \(\eta = (y_3, y_4)\) for any \(y \in \mathbb{R}^d\), we have

\[
R^{4-\alpha} A_3(x) \leq C \int_{R^2} e^{-aR^2 |\eta|^2} \left( \int_{B_{2R}(0,R)} \frac{\partial y}{\partial |\eta|^2} \right) d\eta
\]

\[
\leq C \int_{R^2} e^{-aR^2 |\eta|^2} \left( \int_0^R \frac{r dr}{|\xi - \eta|^2 + r^2} \right) d\eta,
\]
which implies
\[
R^{4\alpha-4} A_3(x) \leq C \int_{\mathbb{R}^n} e^{-\alpha R^2 \frac{|x|^2}{|x - \eta|^2}} d\eta = C \frac{e^{-\alpha |x|^2}}{R} \int_{\mathbb{R}^n} e^{-\alpha |y|^2/4} d\eta \\
\leq C \frac{|x|^2}{R} e^{-\alpha |x|^2/4} + C \frac{e^{-\alpha |y|^2/4}}{R |x|} \int_{\mathbb{R}^n \setminus B(|x|/2)} e^{-\alpha |y|^2} d\eta.
\]
Hence
\[
R^{4\alpha-4} A_3(x) \leq \frac{C}{R(1 + |x|)}.
\]
Since \( \alpha > 1/2 \),
\[
\int_{\partial B_R} A_3(x) d\sigma \leq CR^{3-4\alpha} \int_0^{\pi/2} R^3 \sin \theta \cos \theta d\theta \leq CR^{5-4\alpha} = o(R^3),
\]
Now we can claim (20). For example,
\[
J_5 = \int_{\partial B_R} a (R^{-2}) \times [o(R^{-1}) + O(R^{-1} A_3)] d\sigma = o(1) + O \left( R^{-3} \int_{\partial B_R} A_3(x) d\sigma \right) = o(1).
\]

3.3 Case \( k = 3 \)

Here, we prove the following pointwise estimates for \( A_1 \), \( A_2 \) and \( A_3 \).

**Lemma 3.3** If \( k = 3 \), for any \( R > 2 \) and \( x \in \partial B_R \), we have
\[
(28) \quad A_2(x) \leq CR^{2-4\alpha} \log R, \quad A_2(x) \leq \frac{CR^{2-4\alpha}}{1 + |x|} \quad \text{and} \quad A_3(x) \leq \frac{CR^{3-4\alpha}}{1 + |x|^2},
\]
where \( \mathbf{x} = (x_1, x_2, x_3) \).

With these estimates, we obtain again (20). As the proof is very similar to that for \( A_3(x) \) in the case \( k = 2 \), we just show how to handle \( J_3 \) using (28) and leave other details for interested readers.

As \( \Delta v(x) = o(R^{-2}) + O(R^{-2} A_2) \) for \( |x| = R \),
\[
2|J_3| = \int_{\partial B_R} |x| (\Delta v)^2 d\sigma \leq CR \int_{\partial B_R} o(R^{-4}) d\sigma + CR^{-3} \int_{\partial B_R} \left( \frac{R^{2-4\alpha}}{1 + |x|^2} \right)^2 d\sigma \\
\leq o(1) + CR^{1-8\alpha} \int_{\partial B_R} \frac{d\sigma}{1 + |x|^2}.
\]
Taking the sphere coordinates \( x_4 = r \cos \theta, x_3 = r \sin \theta \cos \varphi \) etc,
\[
\int_{\partial B_R} \frac{d\sigma}{1 + |x|^2} = C \int_0^{\pi} R^3 \sin^2 \theta d\theta \leq CR,
\]
so we have \( |J_3| \leq o(1) + CR^{2-8\alpha} \), which yields \( \lim_{R \to \infty} J_3 = 0 \) when \( \alpha > 1/4 \). The proof is completed.
